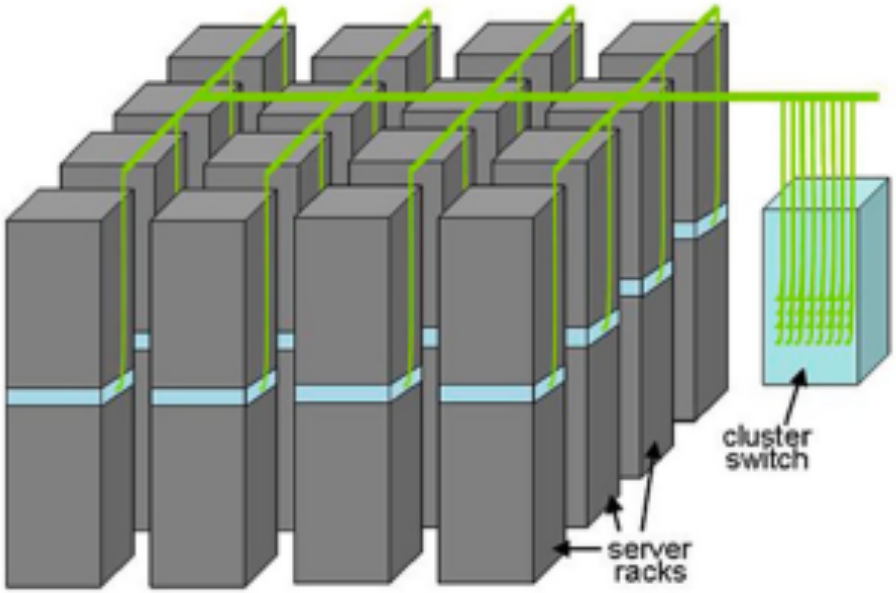
Google's WSCs

WSC Architecture

1U Server:
8 cores,
16 GB DRAM,
4x1 TB disk

Rack:
40-80 severs,
Local Ethernet (1-10Gbps) switch
(30$/1Gbps/server)

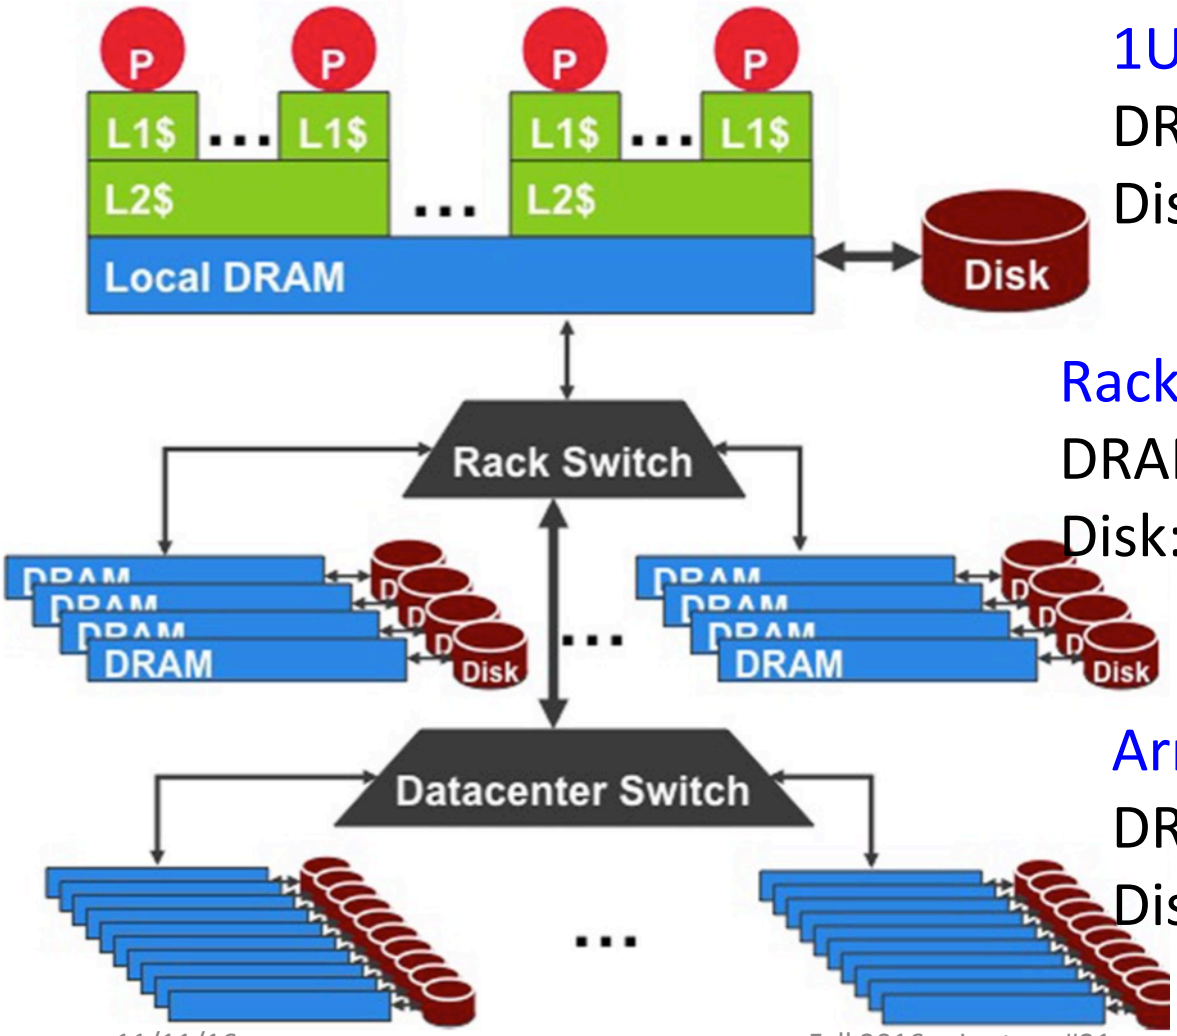


Array (aka cluster):
16-32 racks
Expensive switch
(10X bandwidth → 100x cost)

WSC Storage Hierarchy

Lower latency to DRAM in another server than local disk

Higher bandwidth to local disk than to DRAM in another server



1U Server:

DRAM: 16GB, 100ns, 20GB/s

Disk: 2TB, 10ms, 200MB/s

Rack (80 severs):

DRAM: 1TB, 300us, 100MB/s

Disk: 160TB, 11ms, 100MB/s

Array (30 racks):

DRAM: 30TB, 500us, 10MB/s

Disk: 4.80PB, 12ms, 10MB/s

Google Server Internals

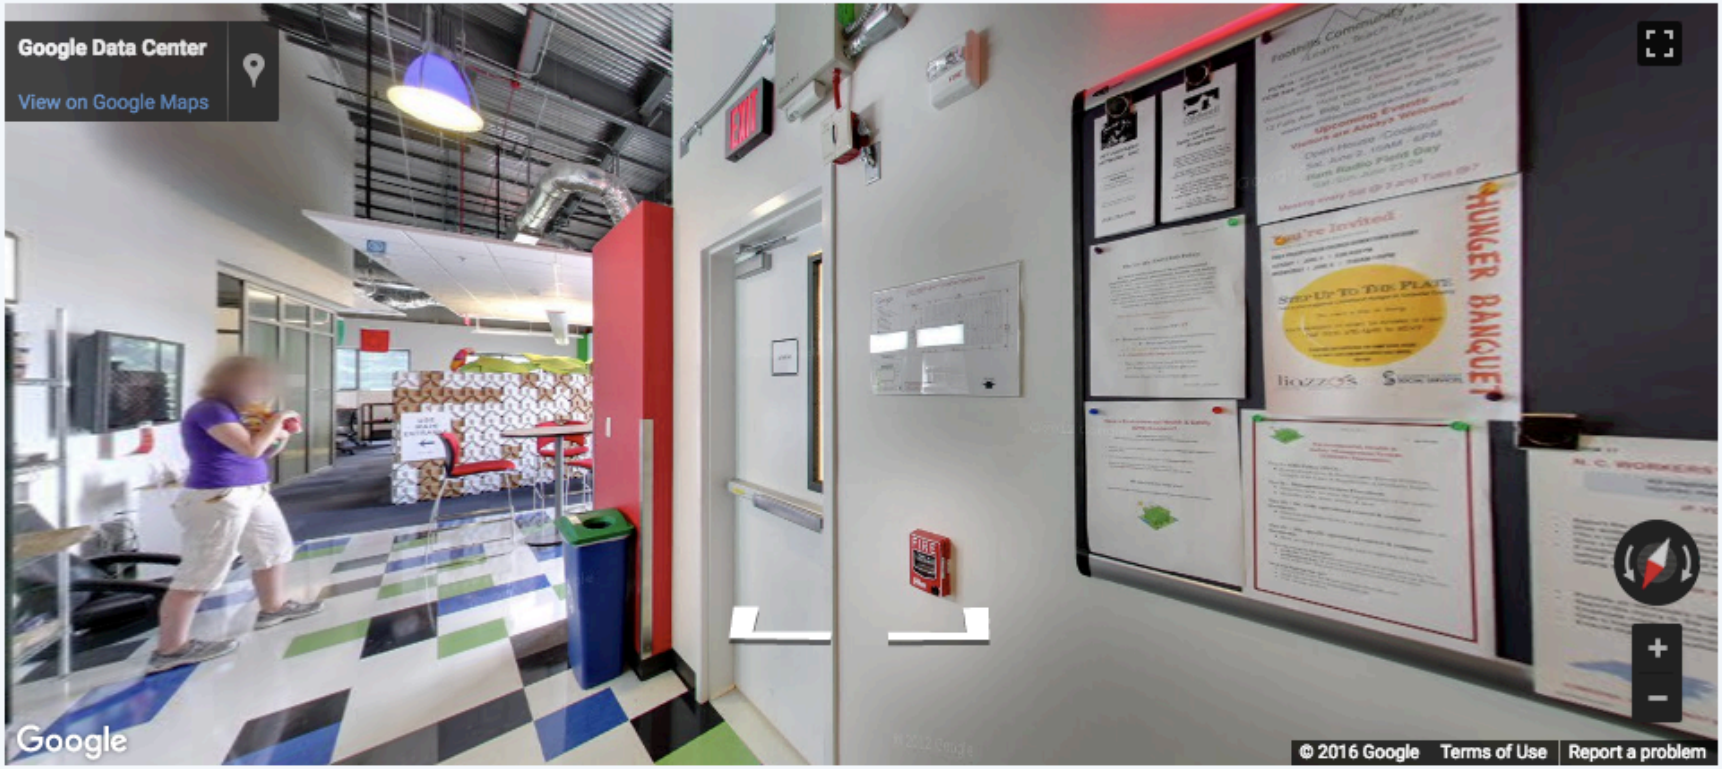
Data centers › Inside look › **Street View**

Take a walk through a Google data center



Google data center - Lenoir, North Carolina

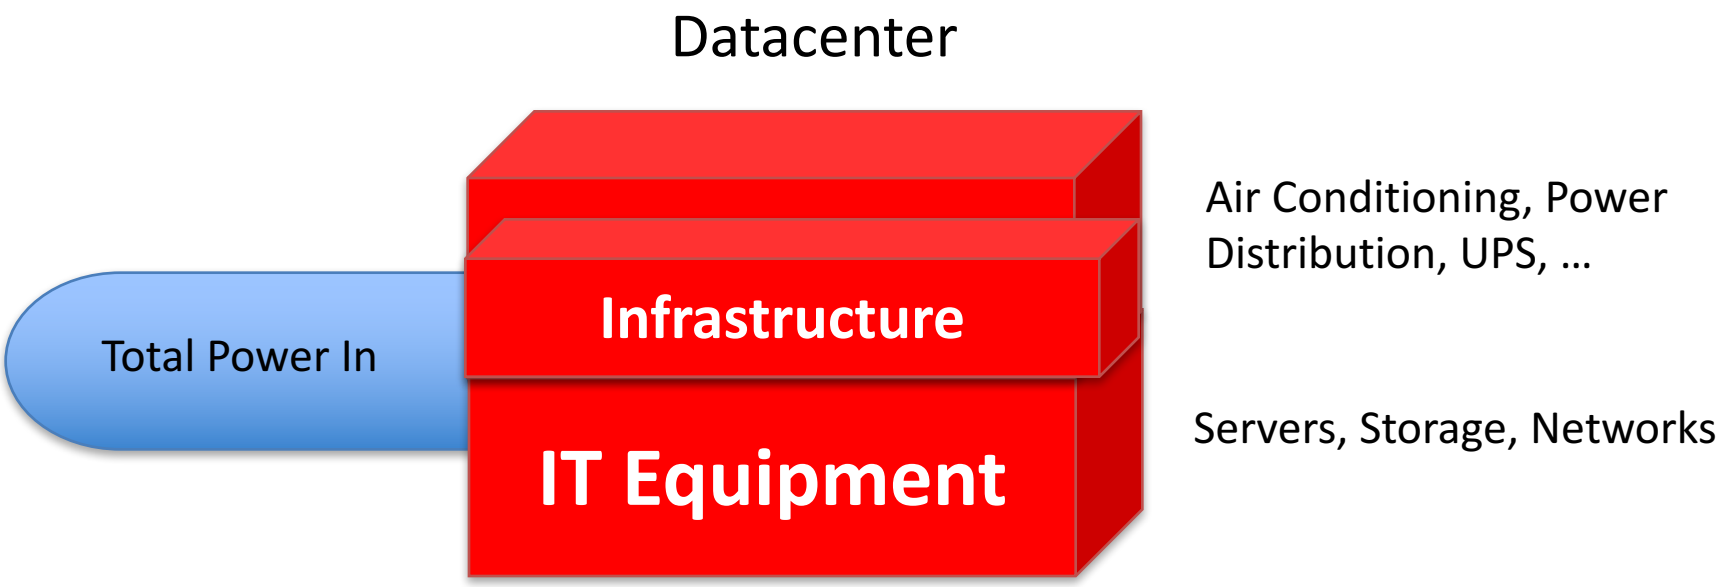
Power Usage Effectiveness

- Energy efficiency
  - Primary concern in the design of WSC
  - Important component of the total cost of ownership
- Power Usage Effectiveness (PUE):

$$\frac{\textbf{Total Building Power}}{\textbf{IT equipment Power}}$$

  - Power efficiency measure for WSC
  - Not considering efficiency of servers, networking
  - Perfection = 1.0
  - Google WSC's PUE = 1.2

Power Usage Effectiveness



PUE = Total Power/IT Power

PUE = 1.5

Energy Proportionality

"The Case for Energy-Proportional Computing,"
Luiz André Barroso,
Urs Hölzle,
IEEE Computer
December 2007

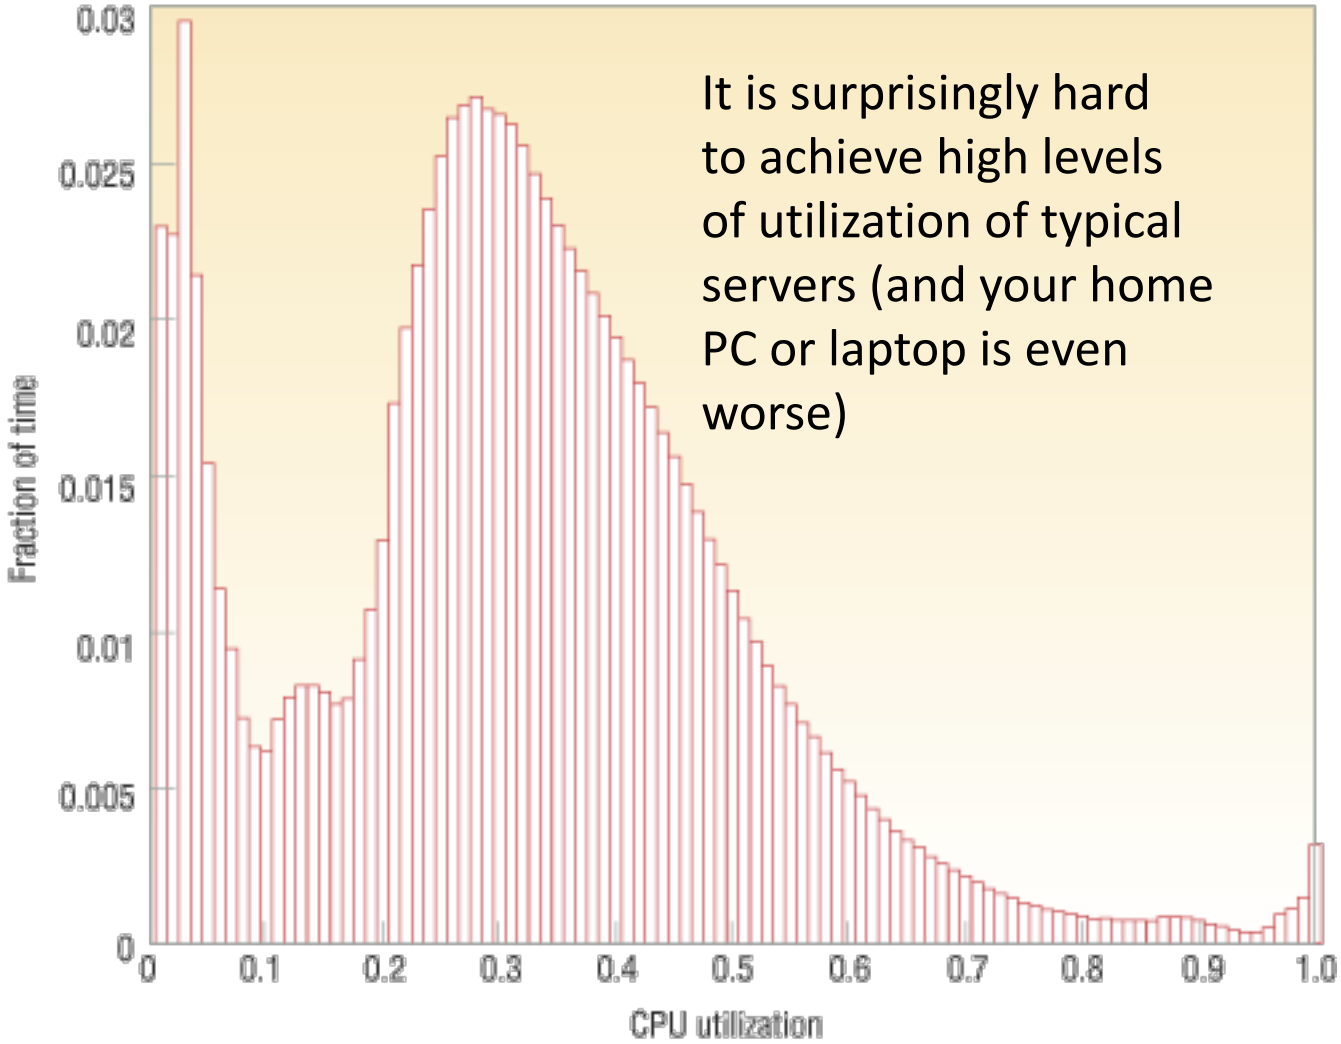


Figure 1. Average CPU utilization of more than 5,000 servers during a six-month period. Servers are rarely completely idle and seldom operate near their maximum utilization, instead operating most of the time at between 10 and 50 percent of their maximum

Energy Proportional Computing

"The Case for Energy-Proportional Computing,"
Luiz André Barroso,
Urs Hölzle,
IEEE Computer
December 2007

Energy Efficiency = Utilization/Power

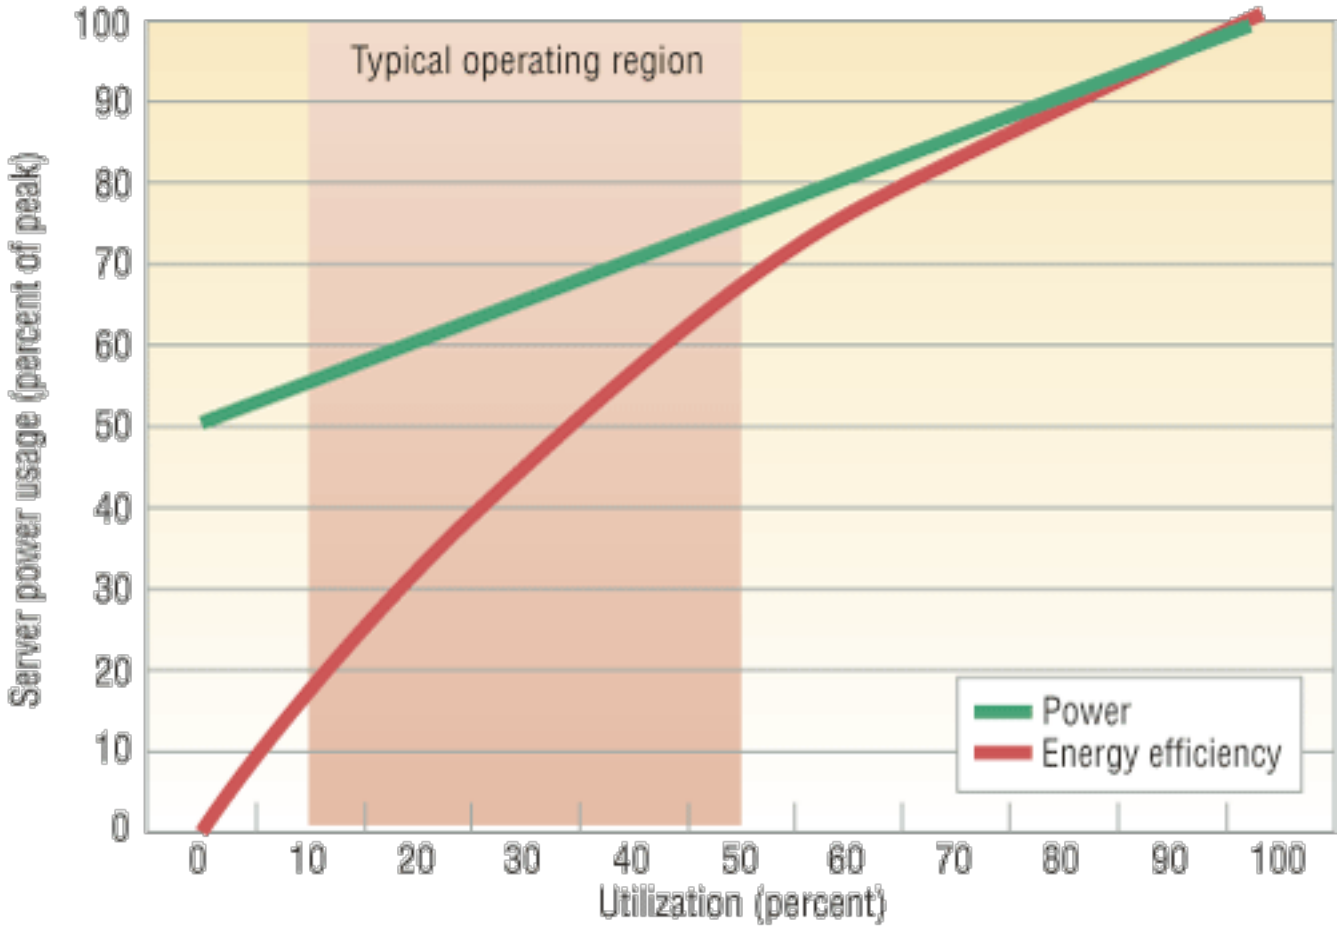

Figure 2. Server power usage and energy efficiency at varying utilization levels, from idle to peak performance. Even an energy-efficient server still consumes about half its full power when doing virtually no work.

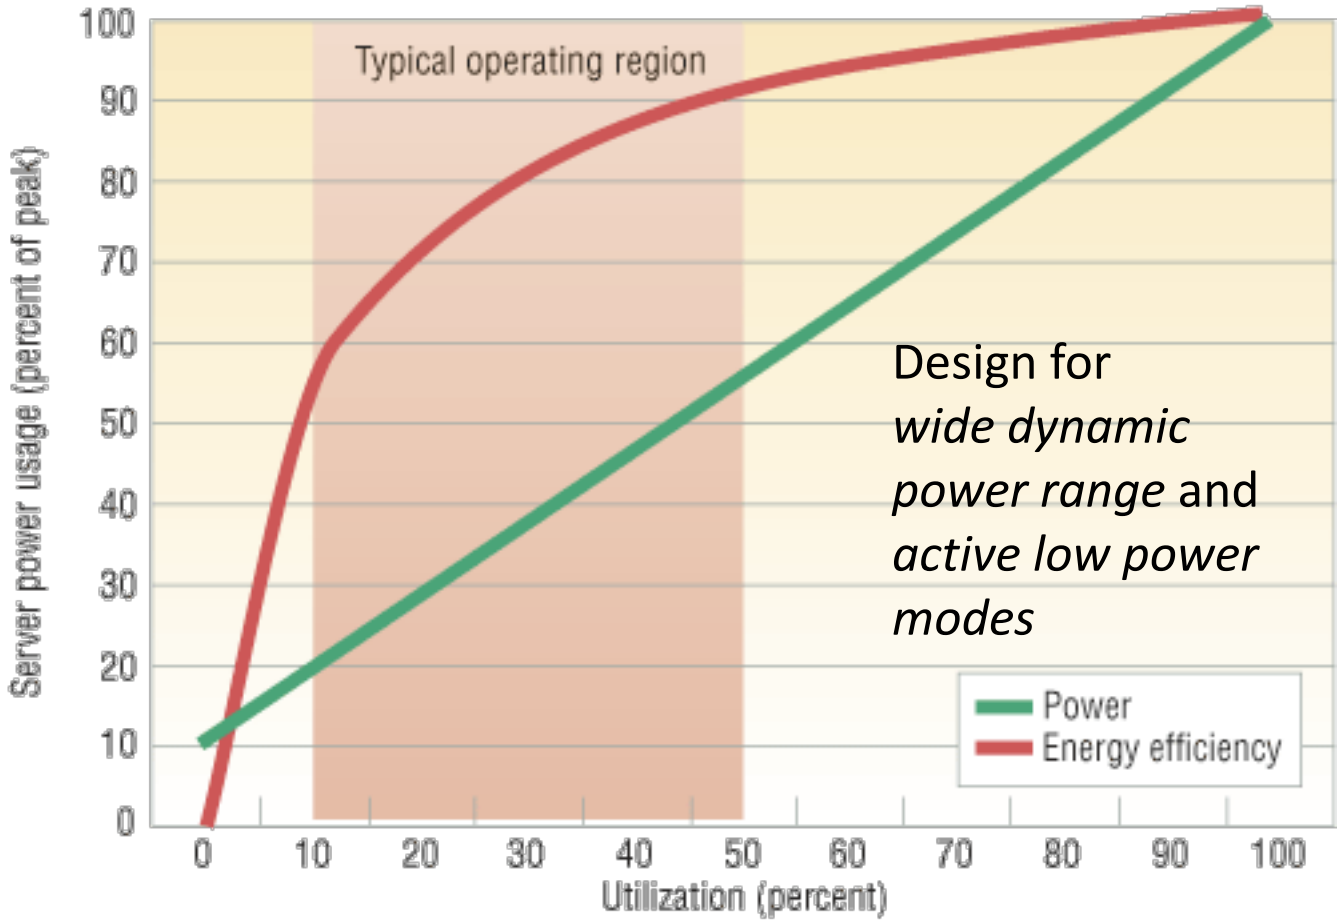
Energy Proportionality

"The Case for Energy-Proportional Computing,"
Luiz André Barroso,
Urs Hölzle,
IEEE Computer
December 2007



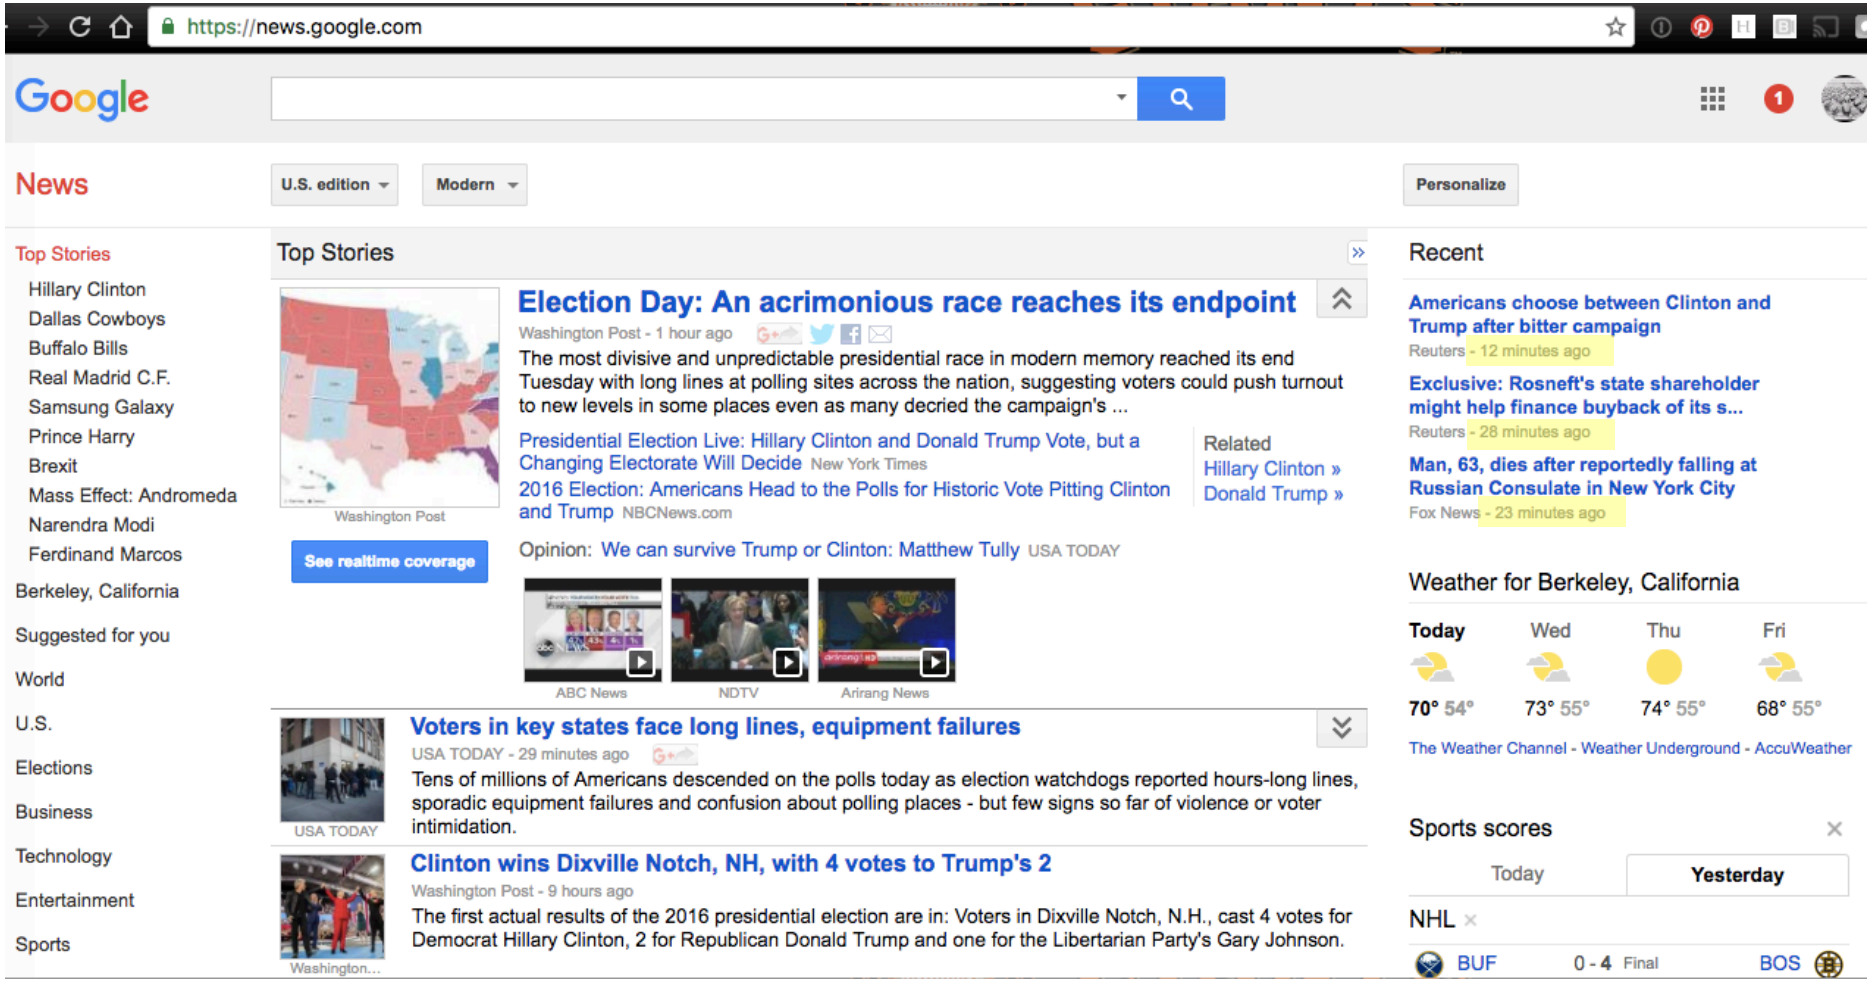
Energy Efficiency = Utilization/Power

Figure 4. Power usage and energy efficiency in a more energy-proportional server. This server has a power efficiency of more than 80 percent of its peak value for utilizations of 30 percent and above, with efficiency remaining above 50 percent for utilization levels as low as 10 percent.

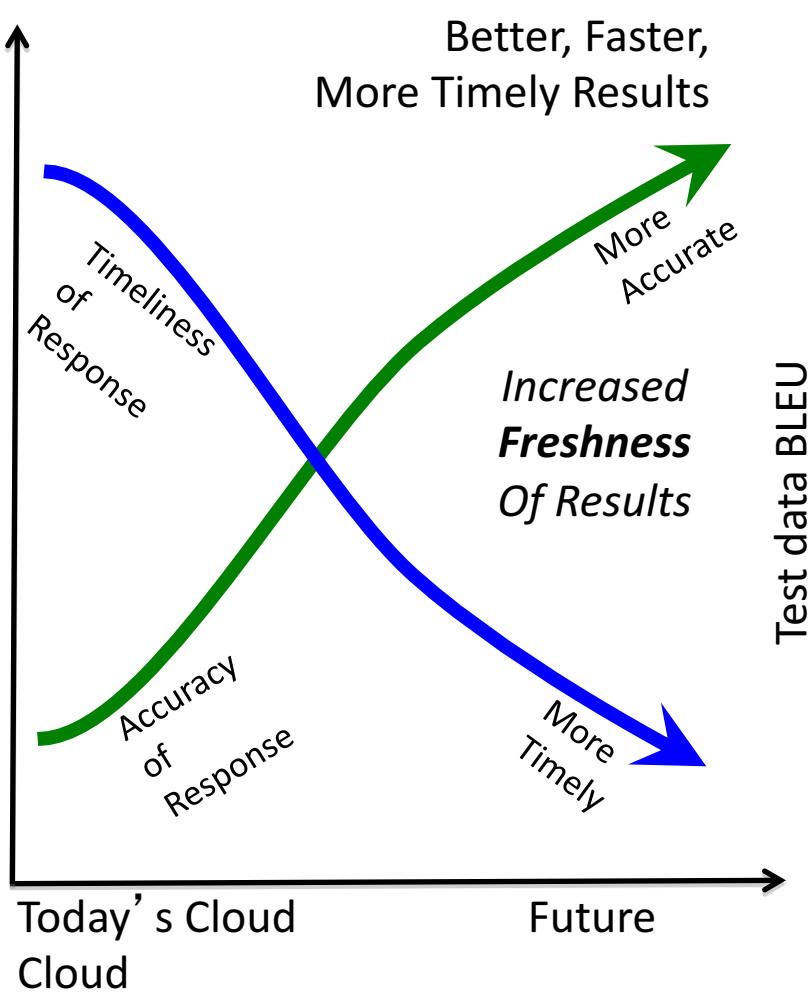
Agenda

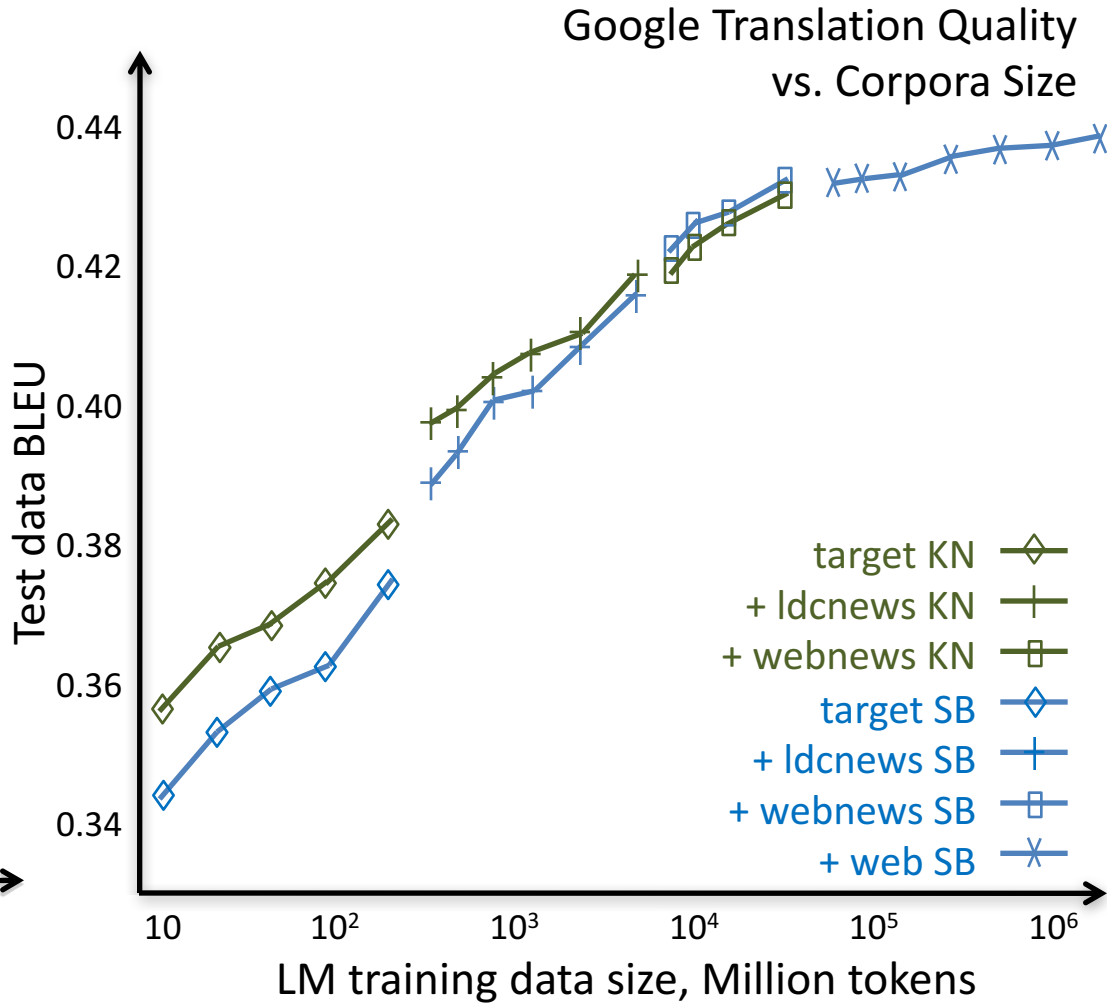
- Warehouse Scale Computing
- Cloud Computing
- Request Level Parallelism (RLP)
- Map-Reduce Data Parallelism
- And, in Conclusion …

Scaled Communities, Processing, and Data



Quality and Freshness



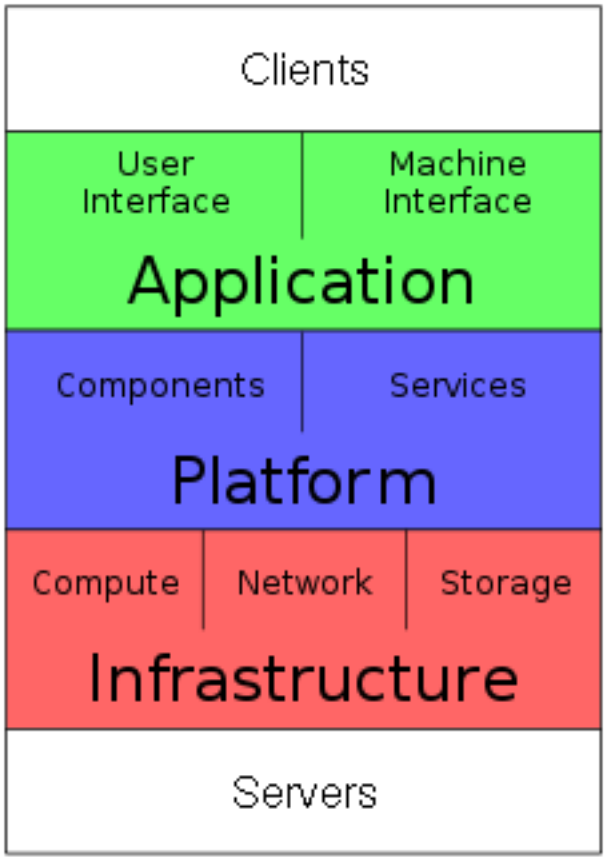


Cloud Distinguished by …

- Shared platform with illusion of isolation
  - Collocation with other tenants
  - Exploits technology of VMs and hypervisors (next lectures!)
  - At best “fair” allocation of resources, but not true isolation
- Attraction of low-cost cycles
  - Economies of scale driving move to consolidation
  - Statistical multiplexing to achieve high utilization/efficiency of resources
- Elastic service
  - Pay for what you need, get more when you need it
  - But no performance guarantees: assumes uncorrelated demand for resources

Cloud Services

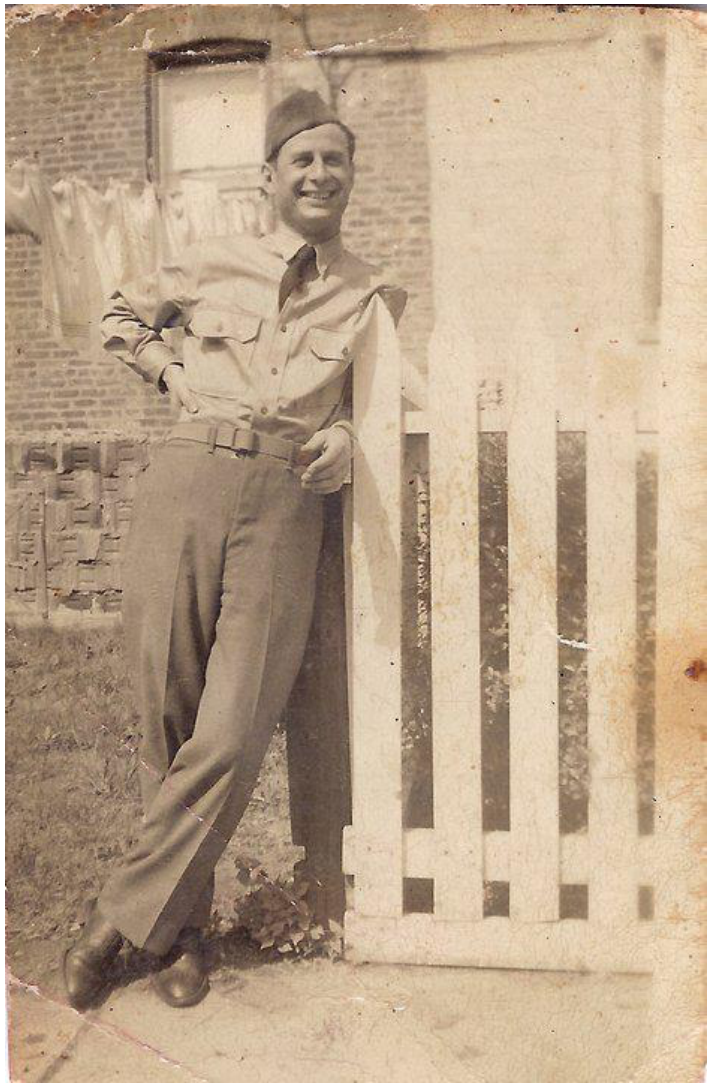
- **SaaS**: deliver apps over Internet, eliminating need to install/run on customer's computers, simplifying maintenance and support
  - E.g., Google Docs, Win Apps in the Cloud
- **PaaS**: deliver computing "stack" as a service, using cloud infrastructure to implement apps. Deploy apps without cost/complexity of buying and managing underlying layers
  - E.g., Hadoop on EC2, Apache Spark on GCP
- **IaaS**: Rather than purchasing servers, sw, DC space or net equipment, clients buy resources as an outsourced service. Billed on utility basis. Amount of resources consumed/cost reflect level of activity
  - E.g., Amazon Elastic Compute Cloud, Google Compute Platform



Cloud Computing Stack

Administrivia

- Midterm II graded and regrade period open until Monday@11:59:59 PM
- What do about Friday labs and Veterans Day?
  - Make ups for Friday labs posted on Piazza
- Project #4-1 released
- Simplified Project #5 coming soon (MapReduce)



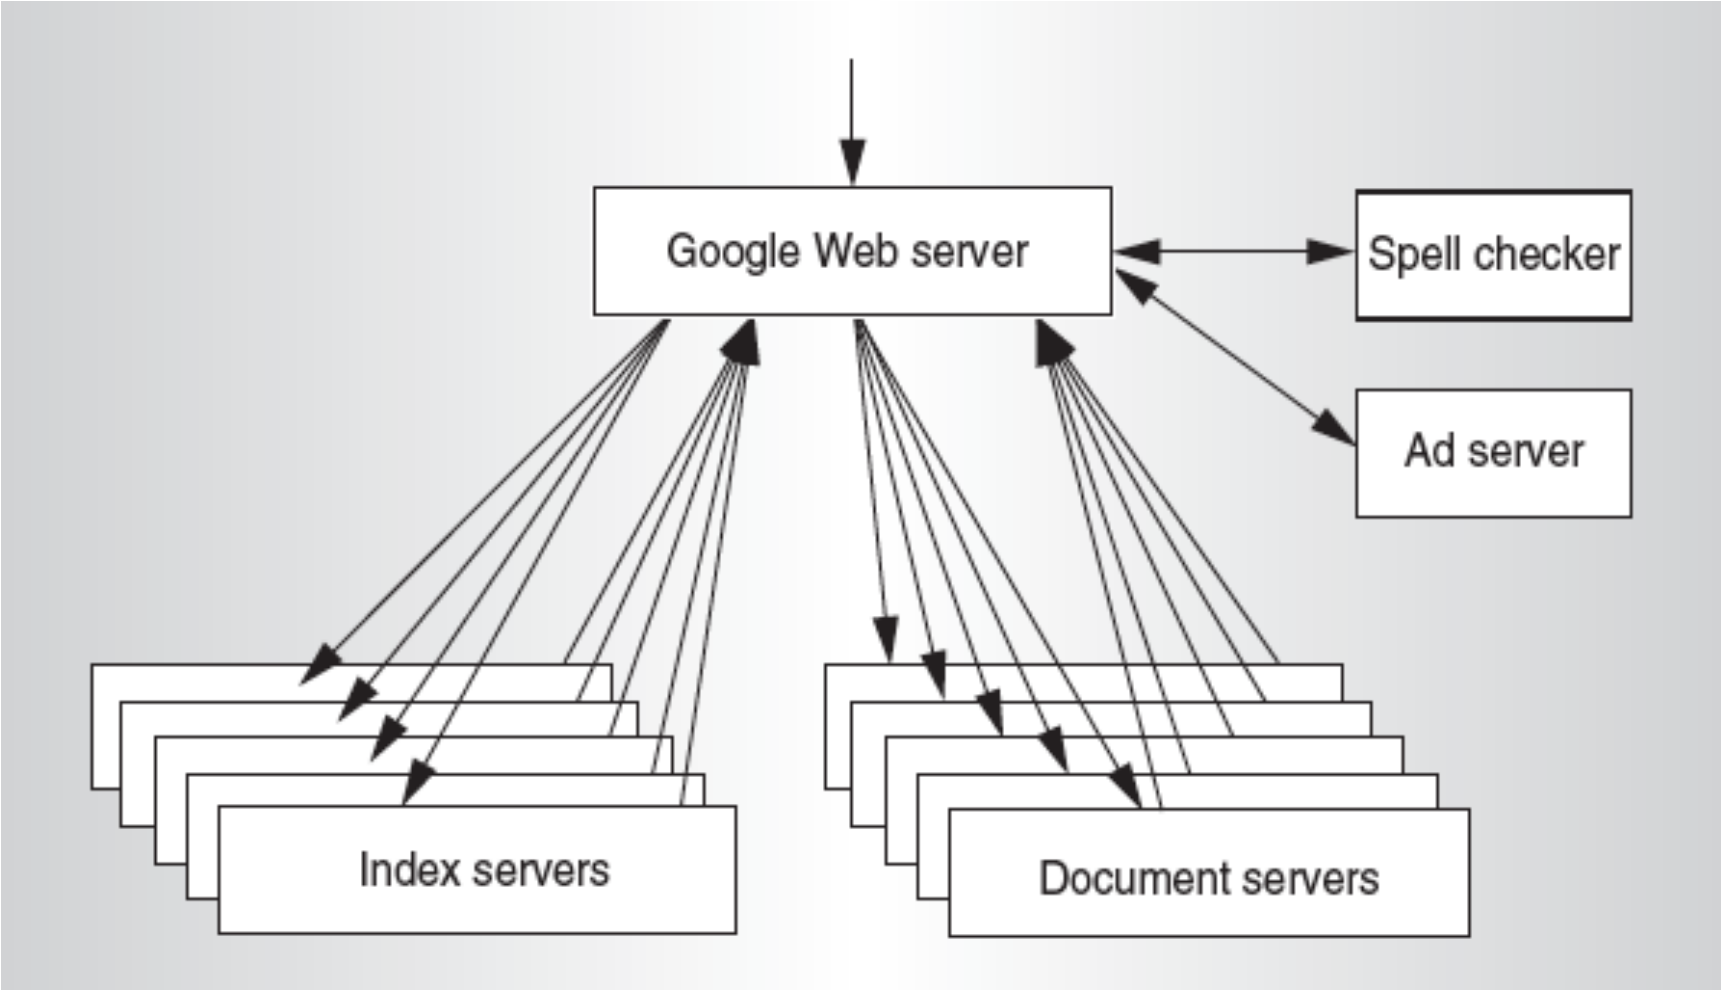
Agenda

- Warehouse Scale Computing
- Cloud Computing
- Request Level Parallelism (RLP)
- Map-Reduce Data Parallelism
- And, in Conclusion …

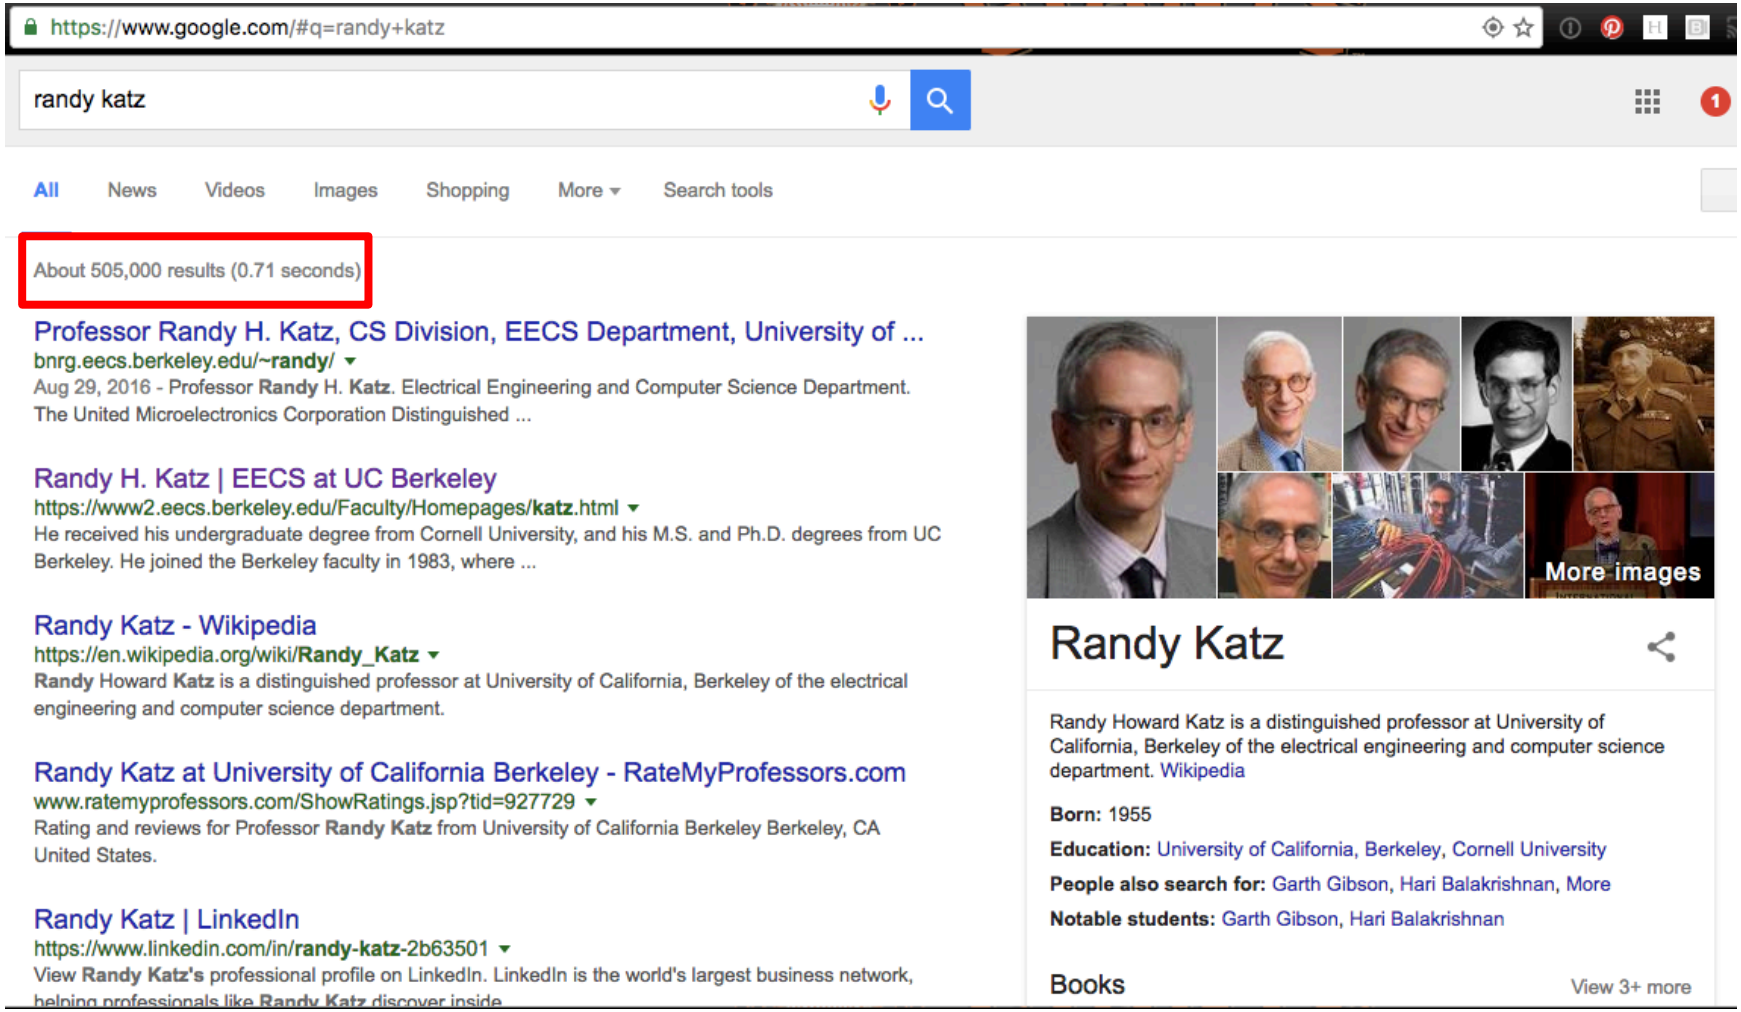
Request-Level Parallelism (RLP)

- Hundreds of thousands of requests per second
  - Popular Internet services like web search, social networking, …
  - Such requests are largely independent
    - Often involve read-mostly databases
    - Rarely involve read-write sharing or synchronization across requests
- Computation easily partitioned across different requests and even within a request

Google Query-Serving Architecture



Web Search Result



Anatomy of a Web Search (1/3)

- Google “Randy Katz”
  1. Direct request to “closest” Google Warehouse Scale Computer
  2. Front-end load balancer directs request to one of many clusters of servers within WSC
  3. Within cluster, select one of many Google Web Servers (GWS) to handle the request and compose the response pages
  4. GWS communicates with Index Servers to find documents that contain the search words, “Randy”, “Katz”, uses location of search as well
  5. Return document list with associated relevance score

Anatomy of a Web Search (2/3)

- In parallel,
  - Ad system: books by Katz at Amazon.com
  - Images of Randy Katz
- Use docids (document IDs) to access indexed documents
- Compose the page
  - Result document extracts (with keyword in context) ordered by relevance score
  - Sponsored links (along the top) and advertisements (along the sides)

Anatomy of a Web Search (3/3)

- Implementation strategy
  - Randomly distribute the entries
  - Make many copies of data (aka “replicas”)
  - Load balance requests across replicas
- ***Redundant copies*** of indices and documents
  - Breaks up hot spots, e.g., “Justin Bieber”
  - Increases opportunities for ***request-level parallelism***
  - Makes the system more ***tolerant of failures***

Agenda

- Warehouse Scale Computing
- Cloud Computing
- Request Level Parallelism (RLP)
- Map-Reduce Data Parallelism
- And, in Conclusion …

Data-Level Parallelism (DLP)

- SIMD
  - Supports data-level parallelism in a single machine
  - Additional instructions & hardware (e.g., AVX)

  e.g., Matrix multiplication in memory

- DLP on WSC
  - Supports data-level parallelism across ***multiple machines***
  - MapReduce & scalable file systems

Problem Statement

- How process large amounts of raw data (crawled documents, request logs, …) every day to compute derived data (inverted indices, page popularity, …) when computation conceptually simple but input data large and distributed across 100s to 1000s of servers so that finish in reasonable time?
- Challenge: Parallelize computation, distribute data, tolerate faults without obscuring simple computation with complex code to deal with issues

Solution: MapReduce

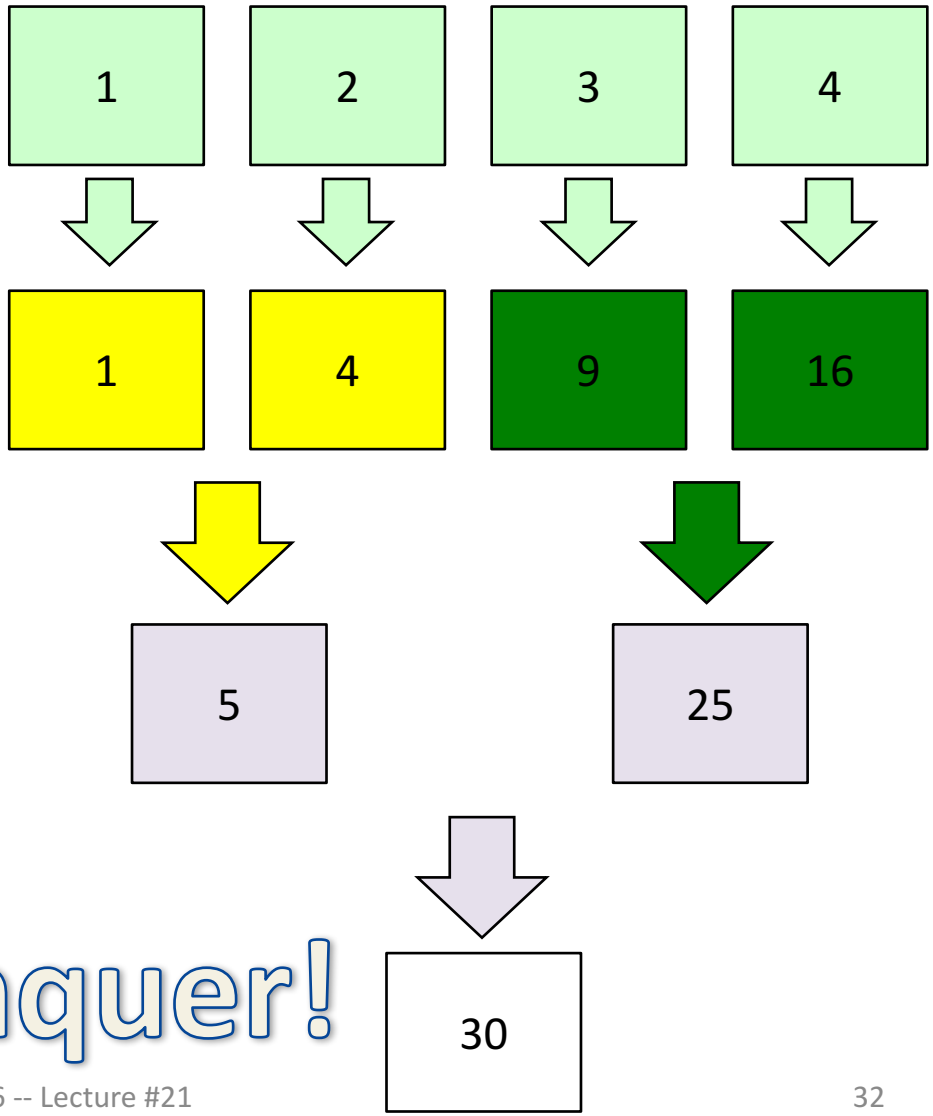
- Simple data-parallel ***programming model*** and ***implementation*** for processing large datasets
- Users specify the computation in terms of
  - a ***map*** function, and
  - a ***reduce*** function
- Underlying runtime system
  - Automatically ***parallelize*** the computation across large scale clusters of machines
  - ***Handles*** machine ***failure***
  - ***Schedule*** inter-machine communication to make efficient use of the networks

Jeffrey Dean and Sanjay Ghemawat, "MapReduce: Simplified Data Processing on Large Clusters," *6th USENIX Symposium on Operating Systems Design and Implementation, 2004*. (optional reading, linked on course homepage – a digestible CS paper at the 61C level)

Inspiration: Map & Reduce Functions, ex: Python

Calculate : $\sum_{n=1}^{4} n^2$

```
A = [1, 2, 3, 4]
def square(x):
    return x * x
def sum(x, y):
    return x + y
reduce(sum,
    map(square, A))
```



Divide and Conquer!

MapReduce Programming Model

- ***Map***: `(in_key, in_value) → list(interm_key, interm_val)`

```
map(in_key, in_val):
   // DO WORK HERE
   emit(interm_key,interm_val)
```

  - Slice data into "shards" or "splits" and distribute to workers
  - Compute set of intermediate key/value pairs

- ***Reduce***: `(interm_key, list(interm_value)) → list(out_value)`

```
reduce(interm_key, list(interm_val)):
   // DO WORK HERE
   emit(out_key, out_val)
```

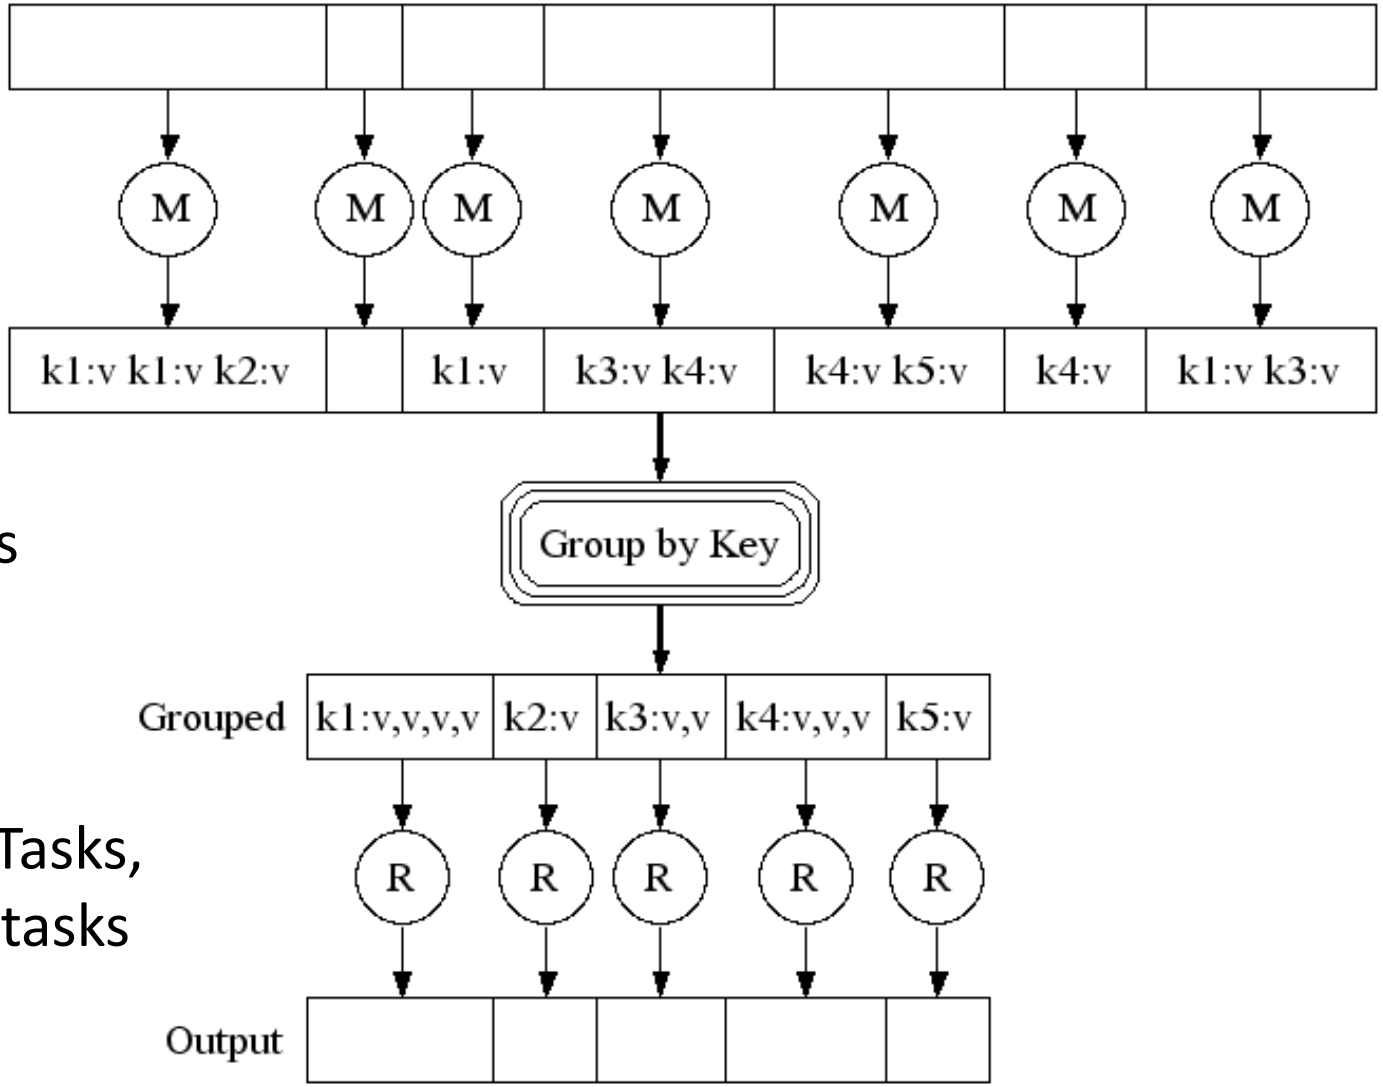
  - Combines all intermediate values for a particular key
  - Produces a set of merged output values (usually just one)

MapReduce Execution

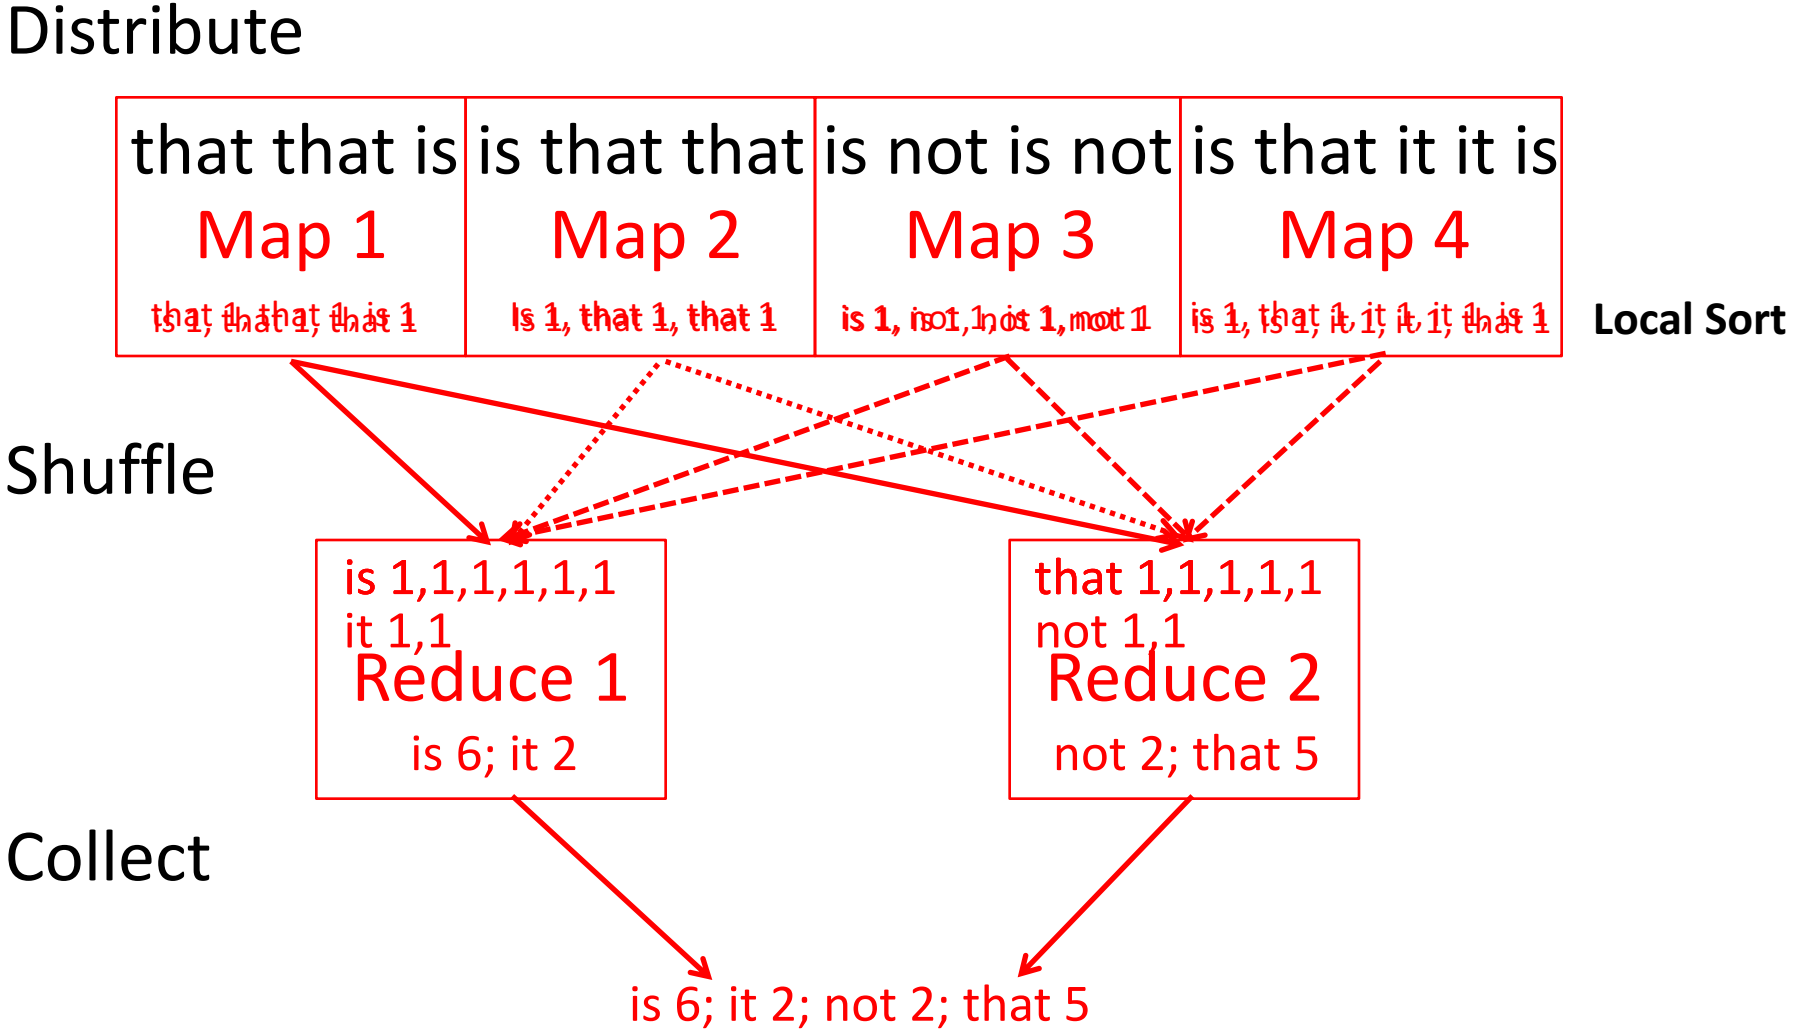
Fine granularity tasks: many more map tasks than machines

Bucket sort to get same keys together

2000 servers =>
≈ 200,000 Map Tasks,
≈ 5,000 Reduce tasks



MapReduce Word Count Example



MapReduce Word Count Example

Task of counting the number of occurrences of each word in a large collection of documents

User-written ***Map*** function reads the document data and parses the words. For each word, it writes the (key, value) pair of (word, 1). The word is treated as the intermediate key and the associated value of 1 means that we saw the word once.

Map phase: (doc name, doc contents) → list(word, count)

```
// "I do I learn" → [("I",1),("do",1),("I",1),("learn",1)]
map(key, value):
  for each word w in value:
    emit(w, 1)
```

MapReduce Word Count Example

Task of counting the number of occurrences of each word in a large collection of documents.

Intermediate data is then sorted by MapReduce by keys and the user's ***Reduce*** function is called for each unique key. In this case, Reduce is called with a list of a "1" for each occurrence of the word that was parsed from the document. The function adds them up to generate a total word count for that word.

Reduce phase: (word, list(counts)) → (word, count_sum)

```
// ("I", [1,1]) → ("I",2)
reduce(key, values):
  result = 0
  for each v in values:
    result += v
  emit(key, result)
```

KEEP
CALM
AND
FINISH
STRONG

The Combiner (Optional)

- One missing piece for our first example:
  - Many times, the output of a single mapper can be "compressed" to save on bandwidth and to distribute work (usually more map tasks than reduce tasks)
  - To implement this, we have the combiner:

```
combiner(interm_key,list(interm_val)):
    // DO WORK (usually like reducer)
    emit(interm_key2, interm_val2)
```

Our Final Execution Sequence

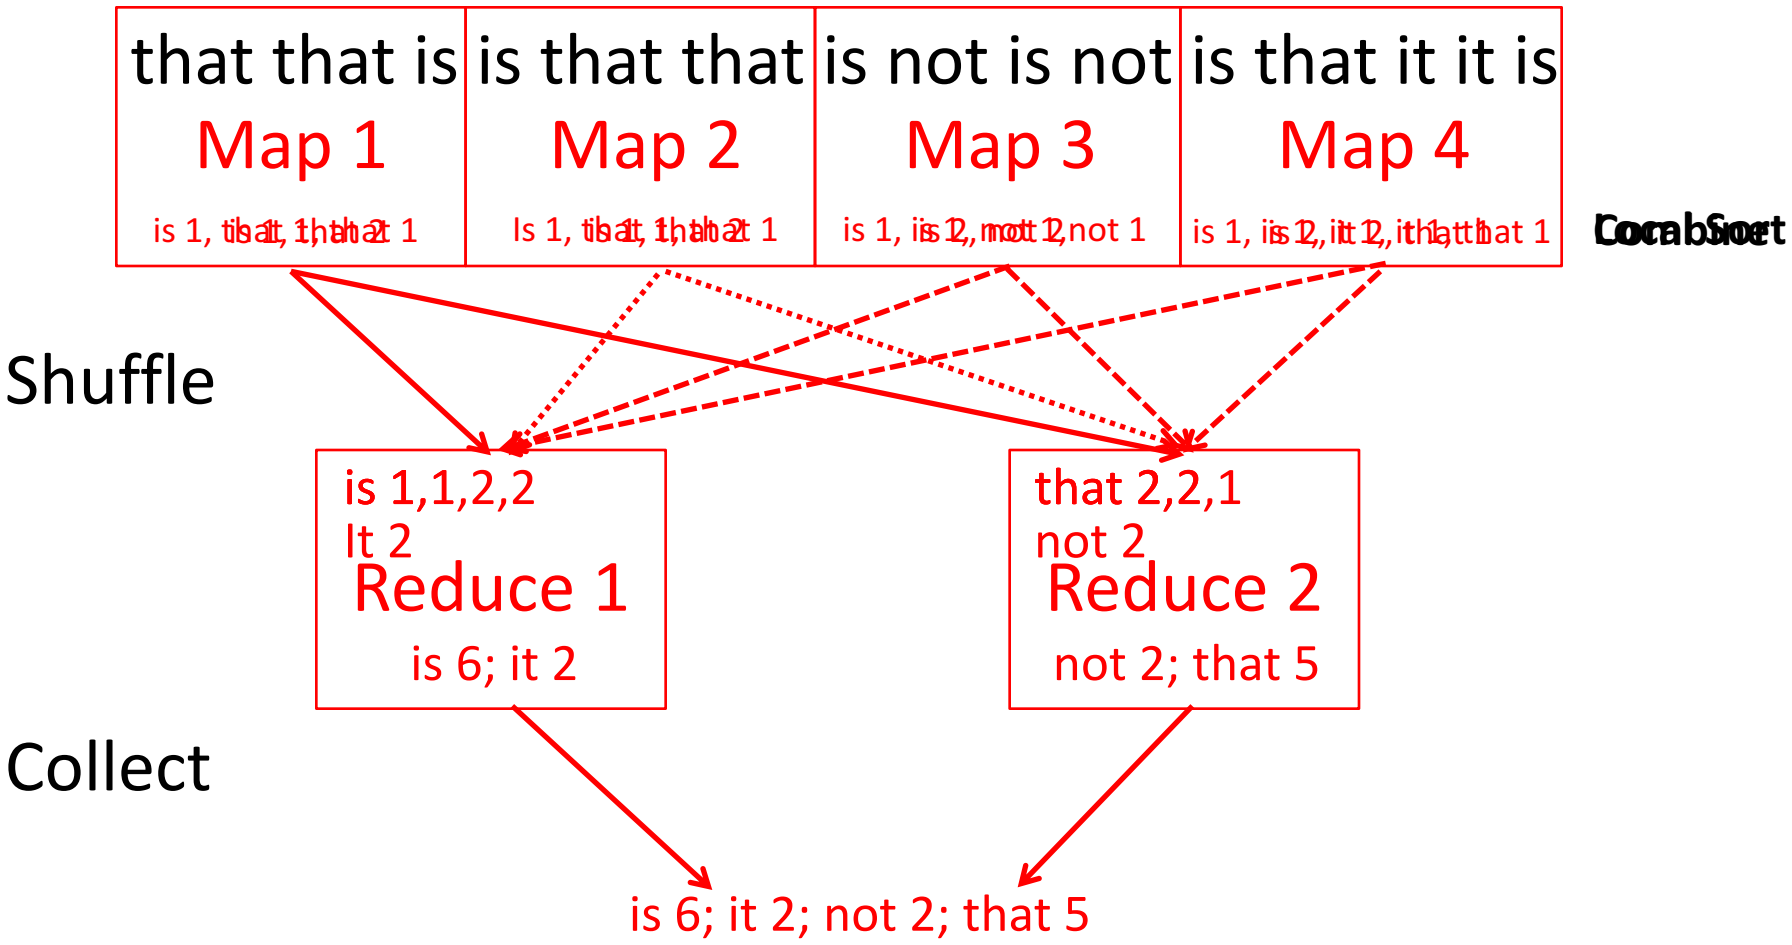
- Map – Apply operations to all input key, val
- Combine – Apply reducer operation, but distributed across map tasks
- Reduce – Combine all values of a key to produce desired output

MapReduce Processing Example: Count Word Occurrences

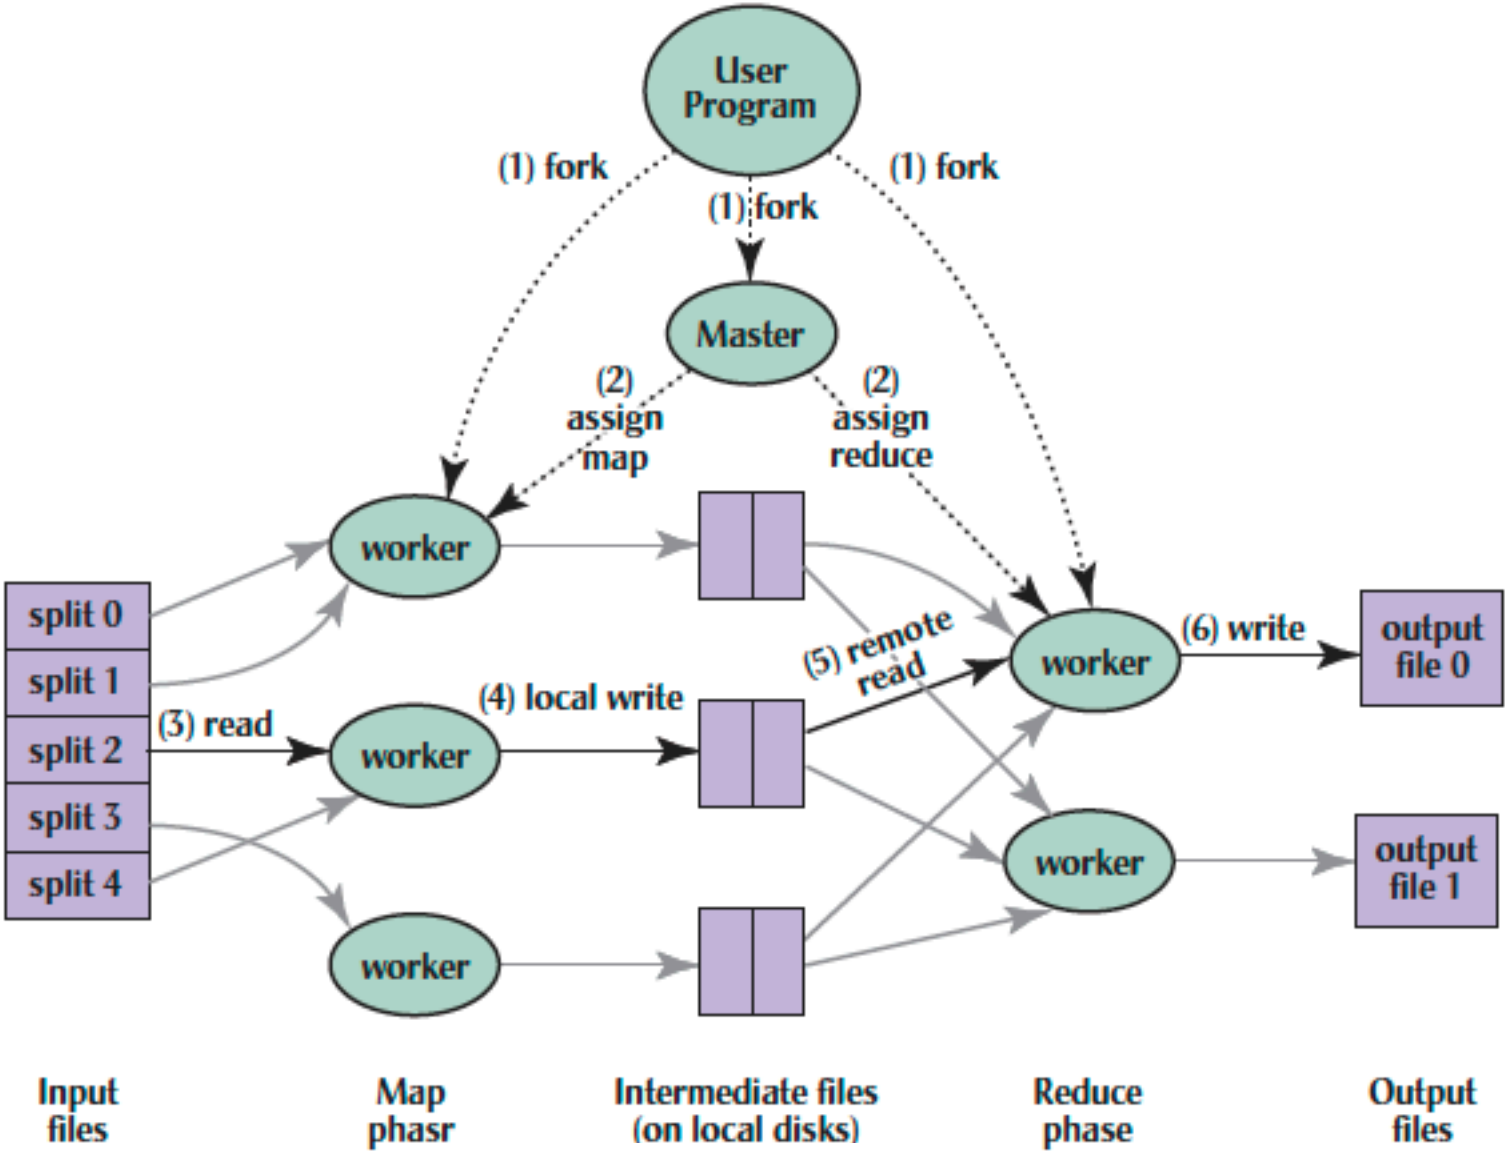
- Pseudo Code: for each word in input, generate <key=word, value=1>
- Reduce sums all counts emitted for a particular word across all mappers

```
map(String input_key, String input_value):
  // input_key: document name
  // input_value: document contents
  for each word w in input_value:
    EmitIntermediate(w, "1"); // Produce count of words
combiner: (same as below reducer)
reduce(String output_key, Iterator intermediate_values):
  // output_key: a word
  // intermediate_values: a list of counts
  int result = 0;
  for each v in intermediate_values:
    result += ParseInt(v); // get integer from key-value
  Emit(output_key, result);
```

MapReduce Word Count Example (with Combiner)



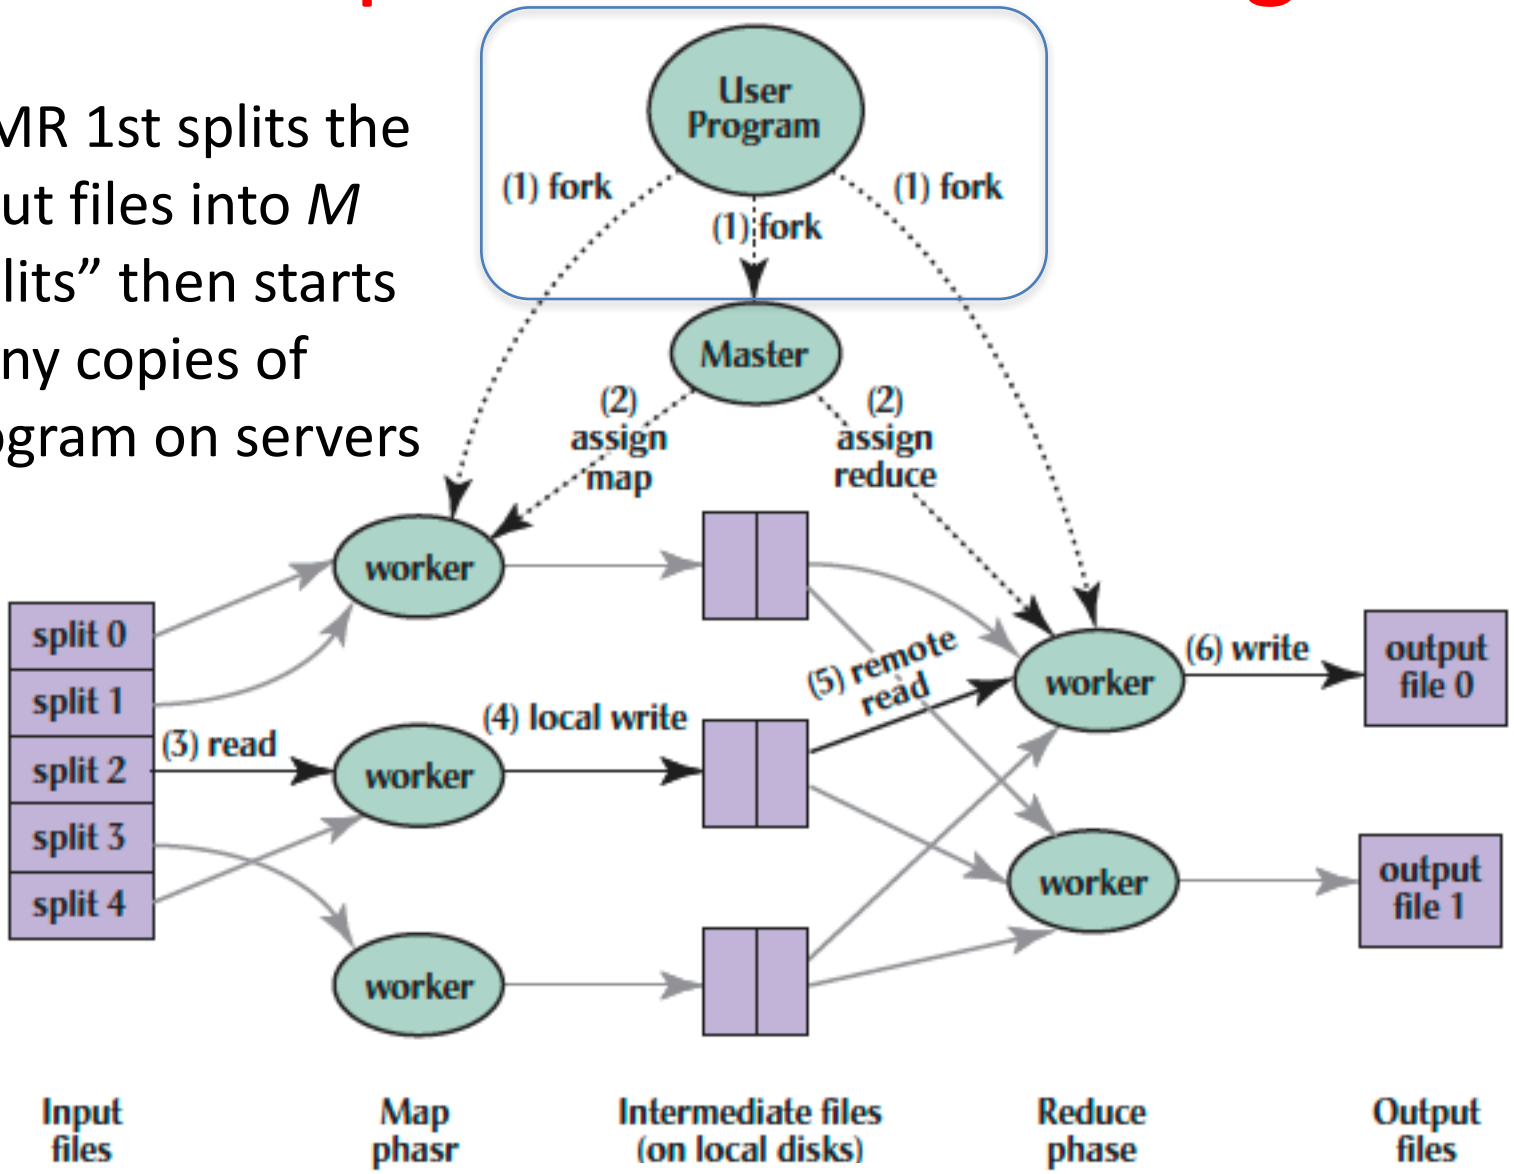
MapReduce Processing



Shuffle phase

MapReduce Processing

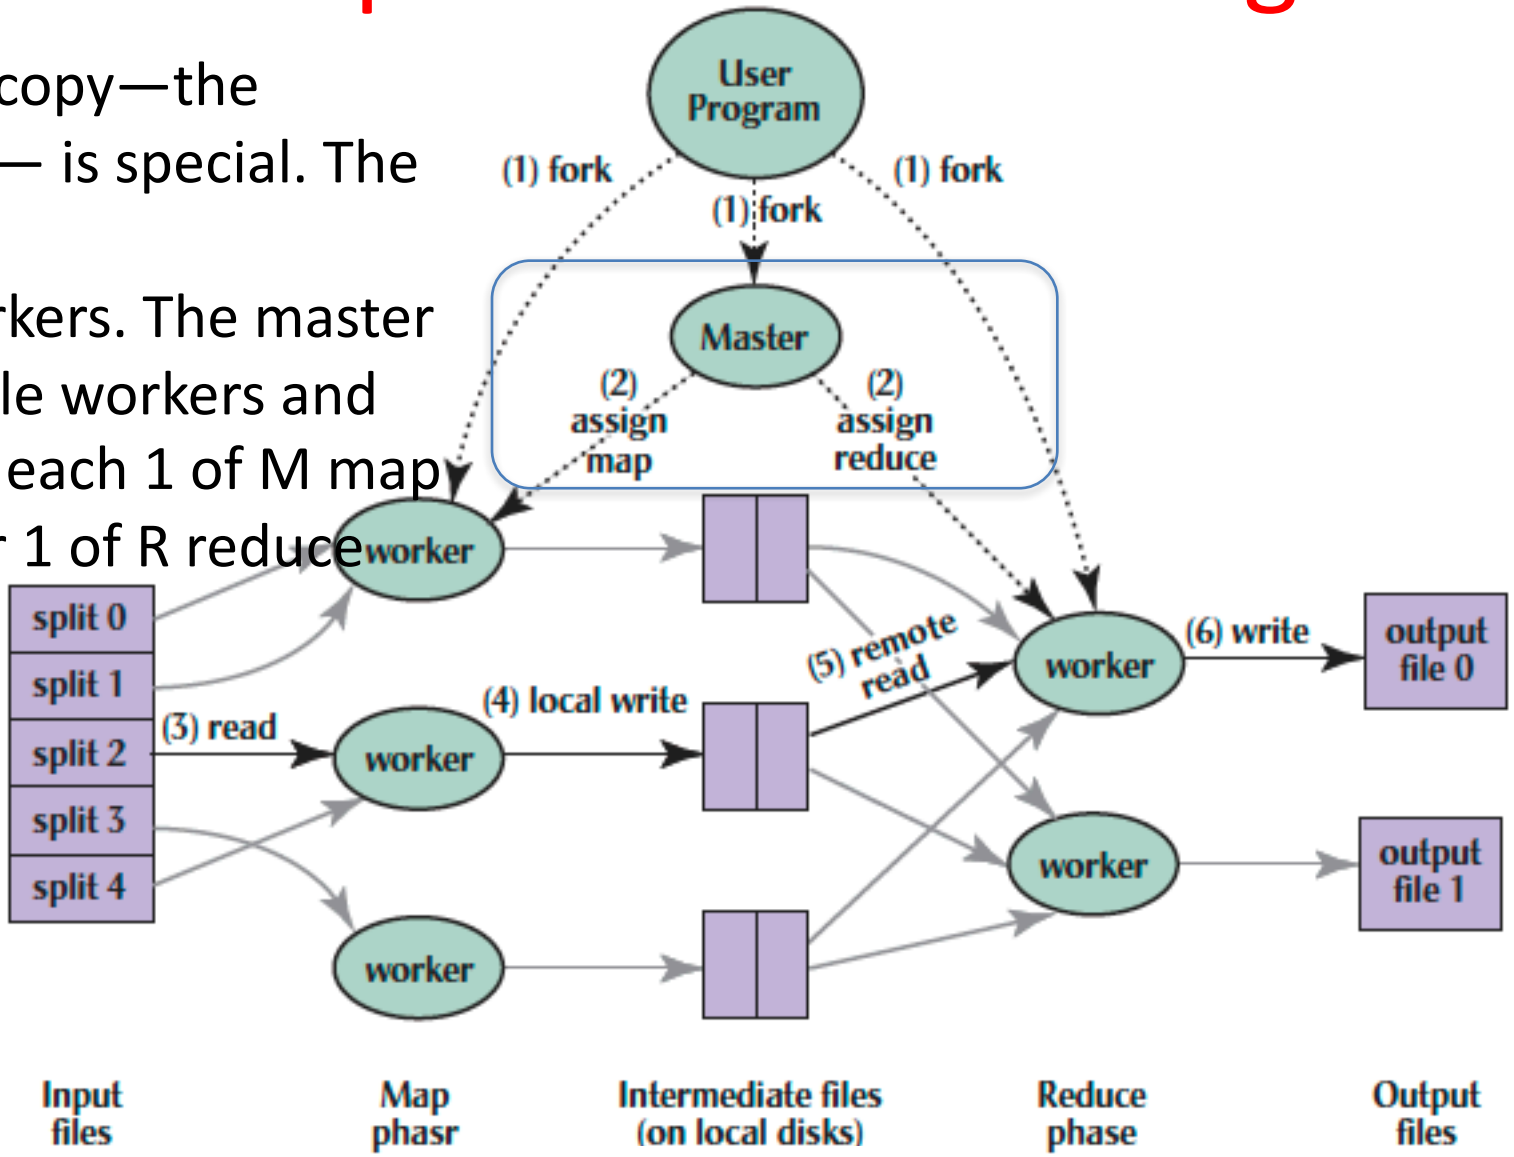
1. MR 1st splits the input files into *M* "splits" then starts many copies of program on servers



Shuffle phase

MapReduce Processing

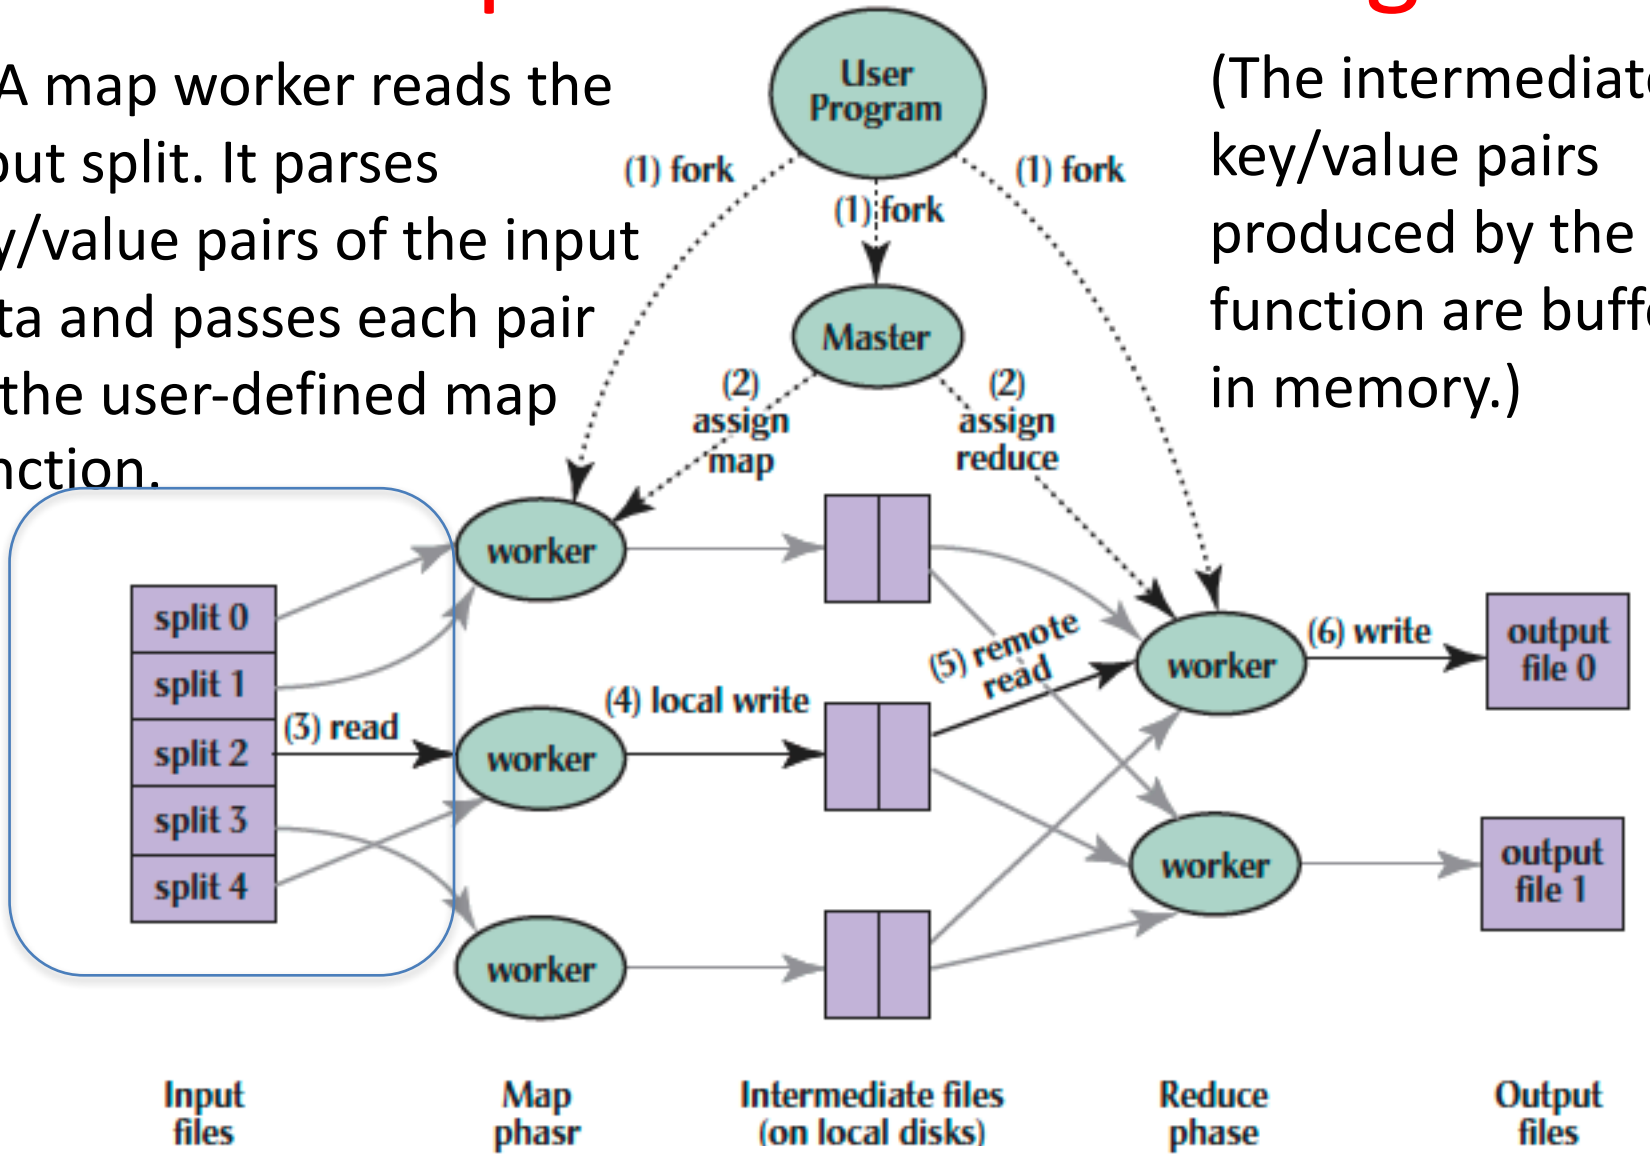
2. One copy—the master— is special. The rest
are workers. The master picks idle workers and assigns each 1 of M map tasks or 1 of R reduce tasks.



Shuffle phase

MapReduce Processing

3. A map worker reads the input split. It parses key/value pairs of the input data and passes each pair to the user-defined map function.

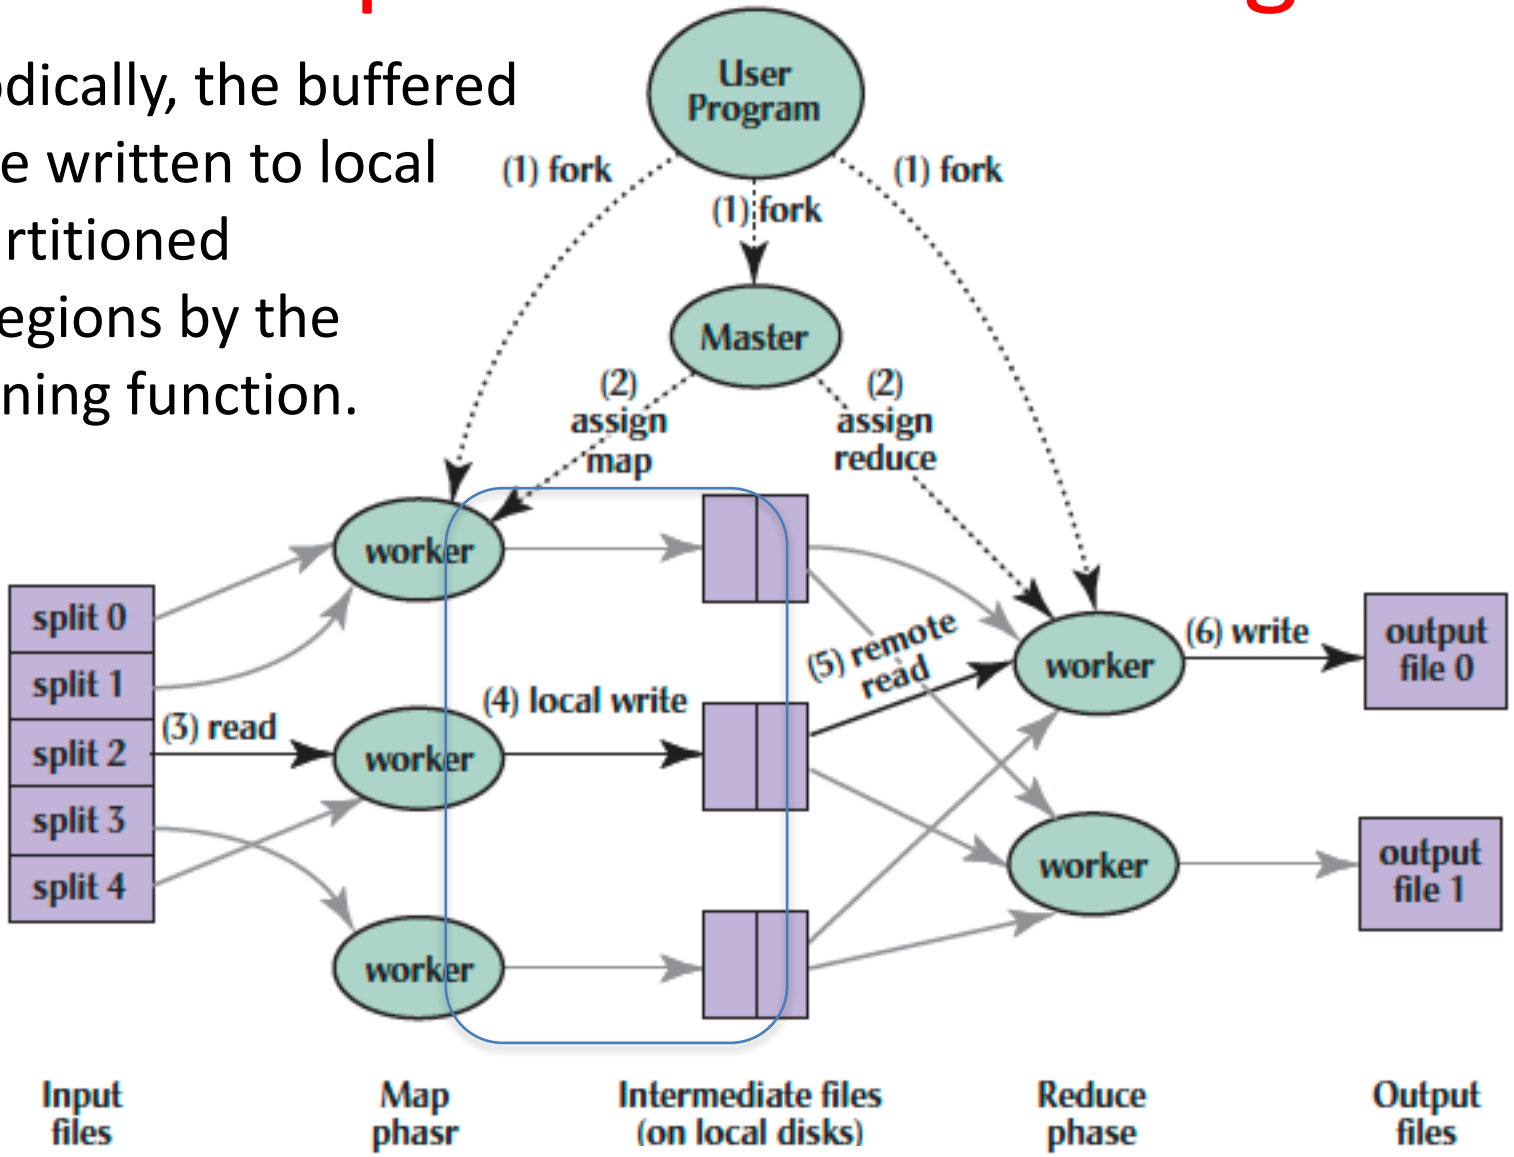


Shuffle phase

(The intermediate key/value pairs produced by the map function are buffered in memory.)

MapReduce Processing

4. Periodically, the buffered pairs are written to local disk, partitioned into *R* regions by the partitioning function.

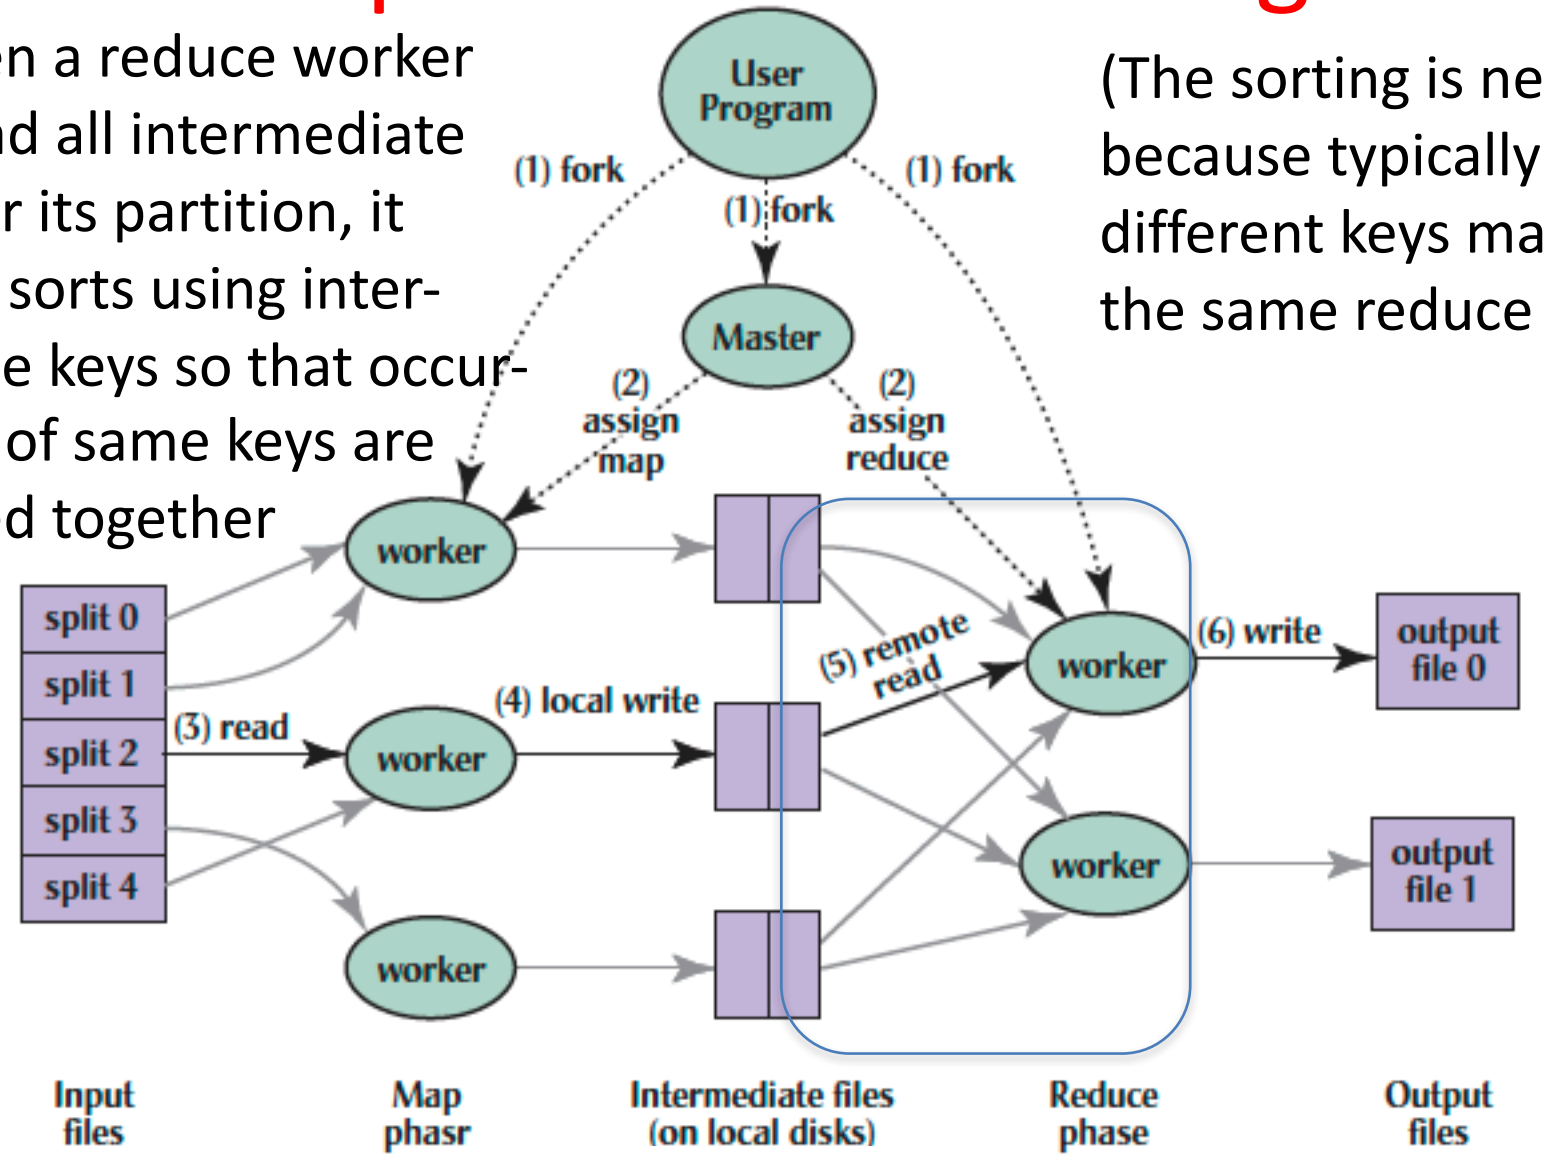


Shuffle phase

MapReduce Processing

5. When a reduce worker has read all intermediate data for its partition, it bucket sorts using inter-mediate keys so that occur-rences of same keys are grouped together

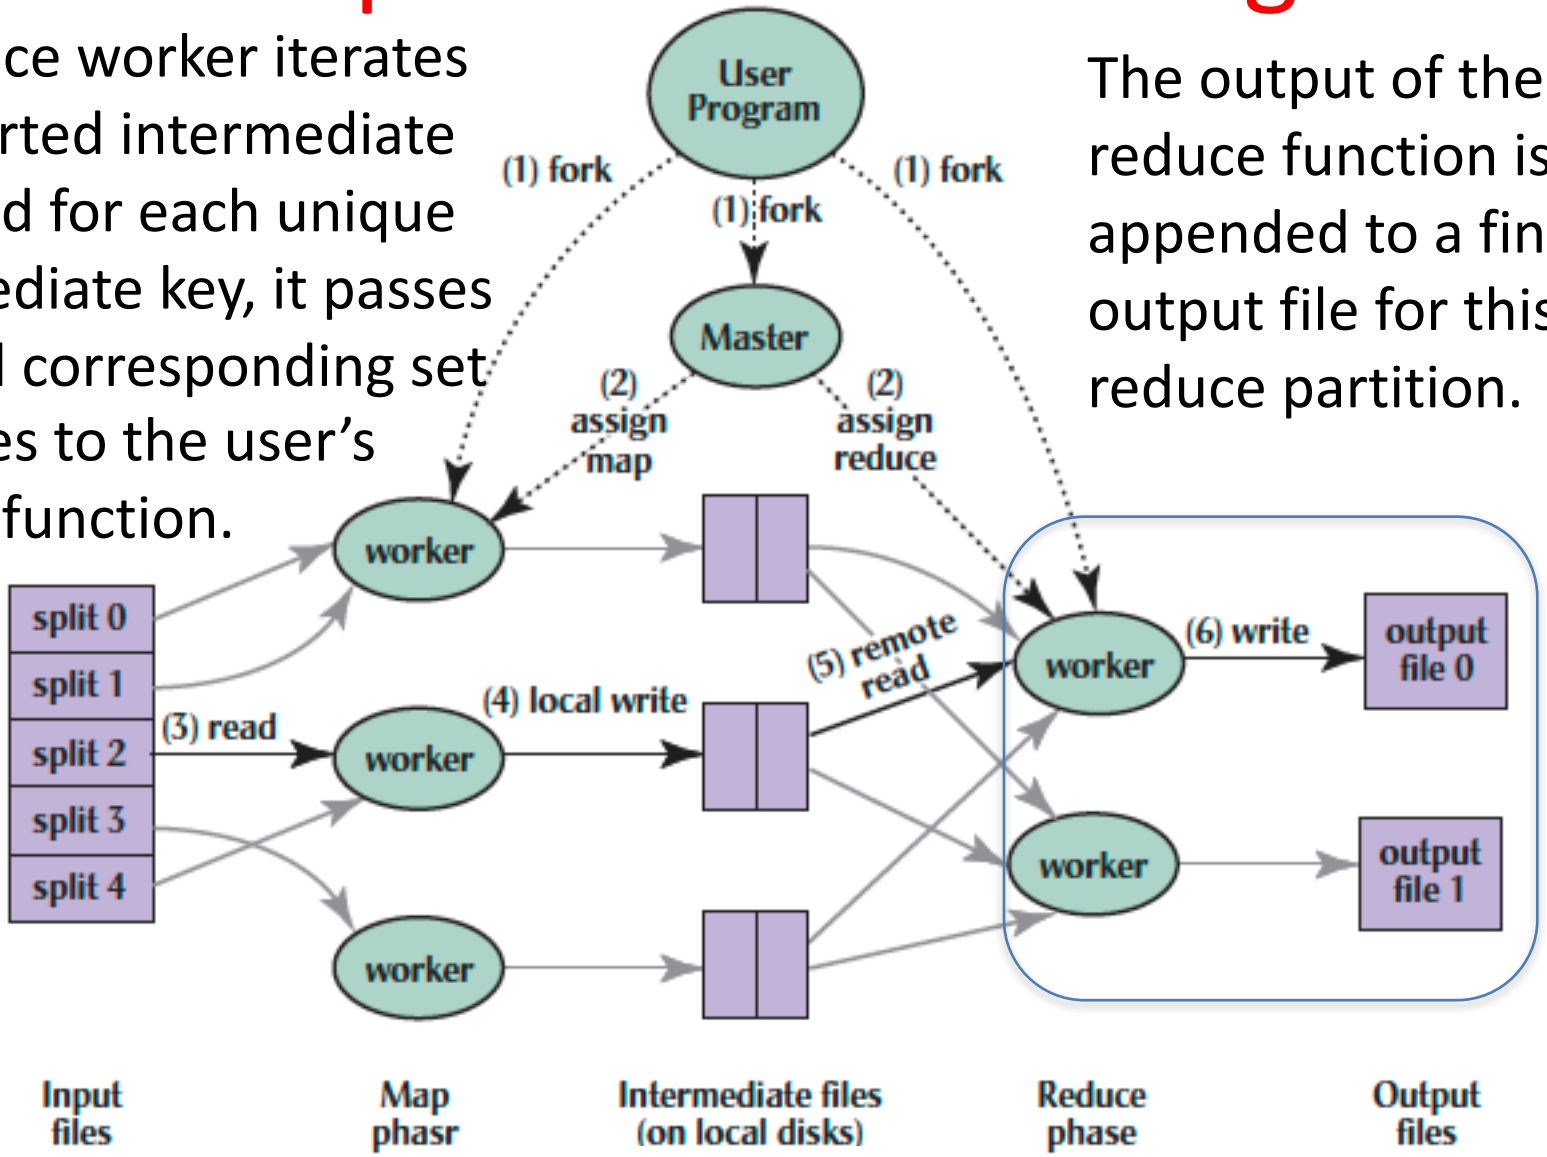
(The sorting is needed because typically many different keys map to the same reduce task)



Shuffle phase

MapReduce Processing

6. Reduce worker iterates over sorted intermediate data and for each unique intermediate key, it passes key and corresponding set of values to the user's reduce function.

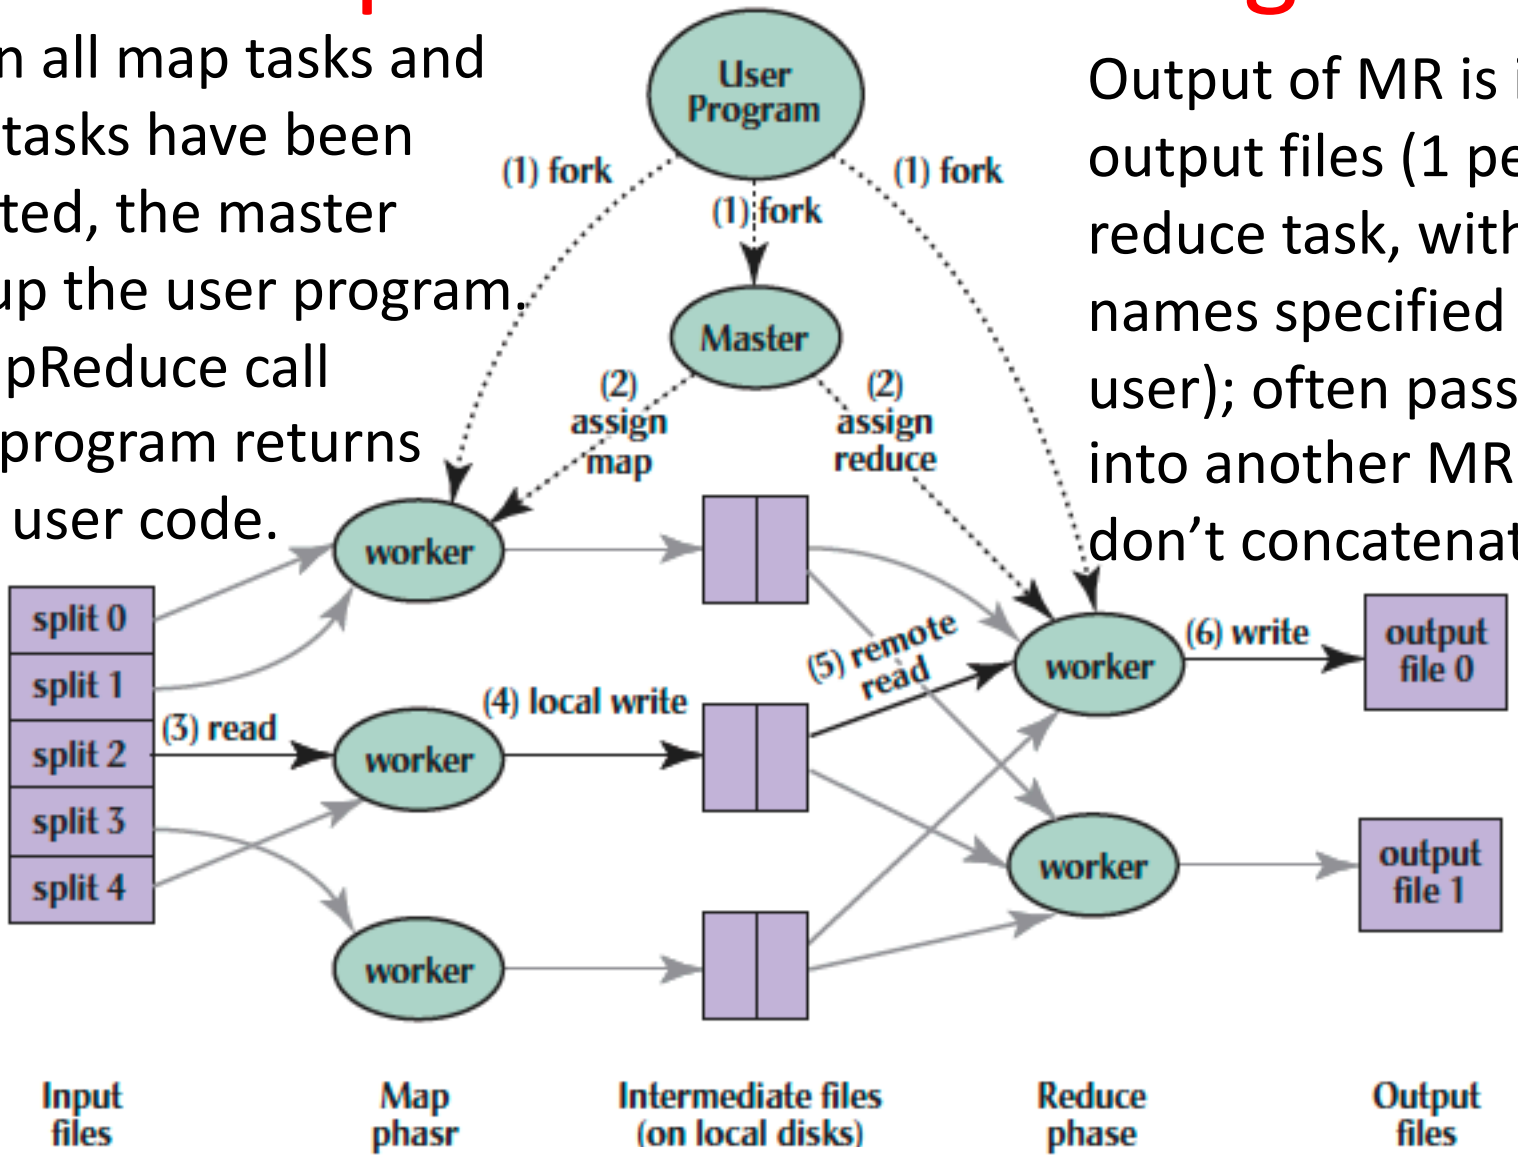


Shuffle phase

The output of the reduce function is appended to a final output file for this reduce partition.

MapReduce Processing

7. When all map tasks and reduce tasks have been completed, the master wakes up the user program. The MapReduce call in user program returns back to user code.



Shuffle phase

Output of MR is in *R* output files (1 per reduce task, with file names specified by user); often passed into another MR job so don't concatenate

Big Data Framework: Hadoop & Spark

- Apache Hadoop
  - Open-source MapReduce Framework
  - Hadoop Distributed File System (HDFS)
  - MapReduce Java APIs

- Apache Spark
  - Fast and general engine for large-scale data processing.
  - Originally developed in the AMP lab at UC Berkeley
  - Running on HDFS
  - Provides Java, Scala, Python APIs for
    - Database
    - Machine learning
    - Graph algorithm

WordCount in Hadoop's Java API

```
public static void main(String[] args) throws IOException {
    JobConf conf = new JobConf(WordCount.class);
    conf.setJobName("wordcount");
    conf.setOutputKeyClass(Text.class);
    conf.setOutputValueClass(IntWritable.class);
    conf.setMapperClass(WCMap.class);
    conf.setCombinerClass(WCReduce.class);
    conf.setReducerClass(WCReduce.class);
    conf.setInputPath(new Path(args[0]));
    conf.setOutputPath(new Path(args[1]));
    JobClient.runJob(conf);
}

public class WCMap extends MapReduceBase implements Mapper {
    private static final IntWritable ONE = new IntWritable(1);
    public void map(WritableComparable key, Writable value,
                    OutputCollector output,
                    Reporter reporter) throws IOException {
        StringTokenizer itr = new StringTokenizer(value.toString());
        while (itr.hasMoreTokens()) {
            output.collect(new Text(itr.next()), ONE);
        }
    }
}

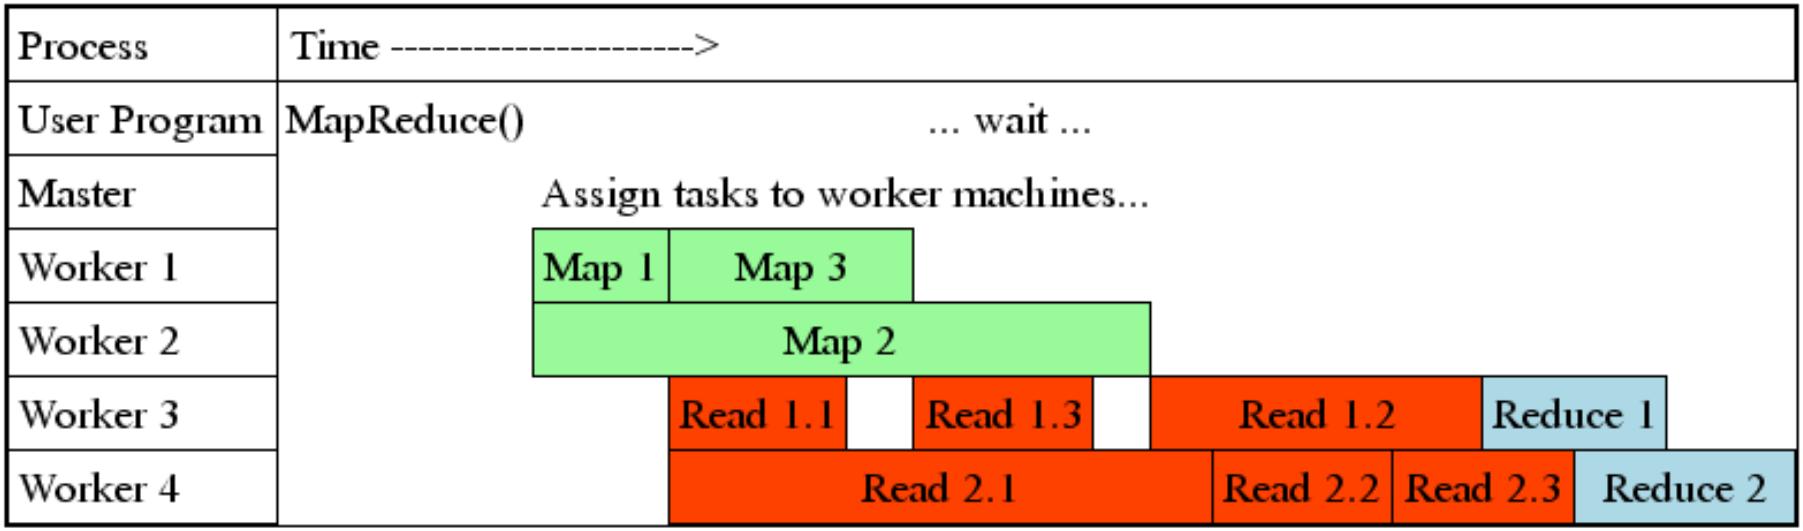
public class WCReduce extends MapReduceBase implements Reducer {
    public void reduce(WritableComparable key, Iterator values,
                       OutputCollector output,
                       Reporter reporter) throws IOException {
        int sum = 0;
        while (values.hasNext()) {
            sum += ((IntWritable) values.next()).get();
        }
        output.collect(key, new IntWritable(sum));
    }
}
```

Word Count in Spark's Python API

```
// RDD: primary abstraction of a distributed collection of items
file = sc.textFile("hdfs://…")
// Two kinds of operations:
// Actions: RDD → Value
// Transformations: RDD → RDD
// e.g. flatMap, Map, reduceByKey
file.flatMap(lambda line: line.split())
    .map(lambda word: (word, 1))
    .reduceByKey(lambda a, b: a + b)
```

See http://spark.apache.org/examples.html

MapReduce Processing Time Line



- Master assigns map + reduce tasks to “worker” servers
- As soon as a map task finishes, worker server can be assigned a new map or reduce task
- Data shuffle begins as soon as a given Map finishes
- Reduce task begins as soon as all data shuffles finish
- To tolerate faults, reassign task if a worker server “dies”

Show MapReduce Job Running

- ~41 minutes total
  - ~29 minutes for Map tasks & Shuffle tasks
  - ~12 minutes for Reduce tasks
  - 1707 worker servers used
- Map (Green) tasks read 0.8 TB, write 0.5 TB
- Shuffle (Red) tasks read 0.5 TB, write 0.5 TB
- Reduce (Blue) tasks read 0.5 TB, write 0.5 TB

And, in Conclusion ...

- Warehouse-Scale Computers (WSCs)
  - New class of computers
  - Scalability, energy efficiency, high failure rate
- Cloud Computing
  - Benefits of WSC computing for third parties
  - "Elastic" pay as you go resource allocation
- Request-Level Parallelism
  - High request volume, each largely independent of other
  - Use replication for better request throughput, availability
- MapReduce Data Parallelism
  - Map: Divide large data set into pieces for independent parallel processing
  - Reduce: Combine and process intermediate results to obtain final result
  - Hadoop, Spark
